2.4 AUGEX MODEL

See schedule 1 for more information and responses relating to this section of the RIN and JEN's approach to running the Augex model.

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
TABLE 2.4.1	AUGEX MODEL INPUTS - ASSET STATUS - SUBTRANSMISSION LINES	<p>Estimated – maximum demand data and route line length</p> <p>Actuals – Line Voltage, Line Ratings</p> <p>Forecast – Average growth per annum</p>	<p>The maximum demand (MD) data requested is weather corrected 50% POE data. This involves adjusting actuals and will therefore be an estimation. In addition JEN does not measure the actual system normal MD on its Subtransmission lines.</p> <p>JEN does not record the route line length of individual subtransmission lines as at December 31 of each year. This was estimated using GIS data.</p>	<p>The actual system normal summer MD data for JEN's subtransmission lines in this table was simulated by running load flow studies in PSSE using the summer non-coincident zone-substation MD actuals. The summer MD actuals were obtained from the JEN Load Demand Forecast as in previous RIN's.</p> <p>The MD data was corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p> <p>The route line length of each line was estimated using Subtransmission line length data extracted from GIS which was used to derive the physical assets circuit length data in previous RIN's. The circuit length data was adjusted using the circuit data sheet to obtain the route length rather than the circuit length.</p>	<p>The actual system normal summer MD data for JEN's subtransmission lines in this table was simulated by running load flow studies in PSSE using the summer non-coincident zone-substation MD actuals.</p> <p>The MD data was then corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p> <p>The route line length of each line was estimated using Subtransmission line length data extracted from GIS which was used to derive the physical assets circuit length data in previous RIN's. The circuit length data was adjusted to obtain the route line</p>	<p>JEN assumes and believes that its method of calculating summer MD's for sub-transmission lines is adequate for use in the augex model.</p> <p>It is also assumed that the application of a single system level weather correction factor to the actual simulated MD data for each line is adequate for use in the augex model.</p> <p>For the route line length calculation it has been assumed that JEN has not installed any new multiple circuit OH line sections in between 2010 and 2014. This is consistent with JEN's standard and projects undertaken in that period.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
				<p>The summer ratings were obtained from JEN planning records of subtransmission line ratings which are based on the circuit data sheets.</p>	<p>length by:</p> <ul style="list-style-type: none"> • deducting lengths determined from the circuit data sheet where there were multiple circuits per pole • Reducing the underground cable lengths where there were multiple cables in a circuit. <p>The forecast % p.a. growth was determined using the difference between the simulated 50% POE 2020 MD MVA loading and the 2014 50% POE MD MVA loading on each line.</p>	<p>JEN does keep records of N-1 emergency ratings for its subtransmission lines. The thermal rating has therefore been inserted under both categories.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
TABLE 2.4.2	AUGEX MODEL INPUTS - ASSET STATUS - HIGH VOLTAGE FEEDERS	<p>Estimated – maximum demand data</p> <p>Actual – Voltage, Route line length, Ratings</p> <p>Forecast – Average growth per annum</p>	<p>The maximum demand (MD) data requested is weather corrected 50%POE data. This involves adjusting actuals and will therefore be an estimation. In addition JENs systems do not record the power factor of HV feeders and the MW loading therefore has to be estimated.</p>	<p>The summer HV feeder MVA MD actuals and ratings were obtained from the JEN Load Demand Forecast as in previous RIN's.</p> <p>The MD data was corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p> <p>The route line length of each line was determined from actuals reported in previous annual RIN's from actual length data extracted from GIS.</p>	<p>The summer HV feeder MVA MD actuals and ratings were obtained from the JEN Load Demand Forecast as in previous RIN's. The MW actuals were calculated by applying the applicable Zone-substation load power factor to the above MVA actuals.</p> <p>The MD data was then corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p> <p>The route line length of each line was determined from actuals reported in previous annual RIN's from actual length data extracted from GIS.</p> <p>JEN does not use different operational ratings for its HV feeders. As such the normal cyclic rating has been used in both columns.</p> <p>The forecast % p.a. growth was determined using the difference between the 50% POE 2020 MD MVA loading and the 50% POE</p>	<p>JEN assumes that the application of a single system level weather correction factor to the actual simulated MD data for each line is adequate for use in the augex model.</p> <p>JEN assumed that using the zone-substation power factor is an adequate representation of the HV feeder power factor.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					corrected actual 2014 MD MVA loading on each line.	
TABLE 2.4.3	AUGEX MODEL INPUTS - ASSET STATUS - SUBTRANSMISSION SUBSTATIONS, SUBTRANSMISSION SWITCHING STATIONS AND ZONE SUBSTATIONS	<p>Estimated – maximum demand data</p> <p>Actual – Substation Voltage, No. of transformers, and Ratings</p> <p>Forecast – Average growth per annum</p>	The maximum demand (MD) data requested is weather corrected 50%POE data. This involves adjusting actuals and will therefore be an estimation.	<p>The summer zone-substation MD actuals and ratings were obtained from the JEN Load Demand Forecast as in previous RIN's.</p> <p>The MD data was corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p> <p>To determine the various ratings JEN has referred to previous regulatory submissions and historical Distribution System Planning Reports to populate these variables. Where a certain rating was not previously reported (i.e. ONAN) this was determined from network planning records.</p>	<p>The summer zone-substation MW and MVA MD actuals were obtained from the JEN Load Demand Forecast as in previous RIN's.</p> <p>The MD data was then corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p> <p>To determine the various ratings JEN has referred to previous regulatory submissions and historical Distribution System Planning Reports to populate these variables. Where a certain rating was not previously reported (i.e. ONAN) this was determined from network planning records. Note that if a 2010 reported rating was found to be incorrect, and was corrected between 2010 and 2014, JEN has corrected the 2010 rating this in this table and for use in the Augex model.</p> <p>The forecast MD data in 2020 was taken using the 2014 JEN Load</p>	<p>JEN assumes that the application of a single system level weather correction factor to the actual simulated MD data for each substation is adequate for use in the augex model.</p> <p>For older transformers in poorer condition, JEN does not operate these transformers beyond its N-1 cyclic rating due to the likelihood of accelerated deterioration. Hence the N-1 2 hour emergency rating is assumed to be the same as the N-1 cyclic rating for these transformers. This is consistent with JEN asset management approach.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>Demand Forecast. To run properly in the model these MD's were corrected to remove the effect of committed augmentation projects in 2015 (i.e. new zone-substation BMS).</p> <p>The forecast % p.a. growth was determined using the difference between the 50% POE 2020 MD MVA loading and the 50% POE corrected actual 2014 MD MVA loading on each substation.</p> <p>For table 2.4.5 and to run the augex model JEN has split its zone-substations in the forecast period only into 2 separate categories. The 2 categories are the zone-substations that had negative growth (ID 4) and those that had positive growth (ID 3). This was done to capture the differences in utilisation profiles for JEN's growth and no growth regions across its network. The network ID in this table represents the forecast network ID in table 2.4.5 with the historical period being ID 2.</p>	
TABLE 2.4.4	AUGEX MODEL INPUTS -	Estimated – maximum demand data	The maximum demand (MD) data requested is weather corrected 50%POE data. This involves adjusting actuals and	The estimated maximum demand data and cyclic ratings for each substation were derived using customer metered data linked to the appropriate distribution	JEN has used metered data to calculate the MD on its substations by summing the relevant meters. Each meter is	JEN assumes that the application of a single system level weather correction factor to the actual simulated MD data for each substation is

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
	ASSET STATUS - DISTRIBUTION SUBSTATIONS	<p>Actual - cyclic ratings of distribution substations</p> <p>Forecast – Average growth per annum</p>	<p>will therefore be an estimation.</p> <p>In addition distribution substation loading data is estimated since JEN does not have meters on each substation.</p>	<p>substation by JEN's GIS network model.</p> <p>The MD data was corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p>	<p>associated with the relevant distribution substation by JEN's network model in GIS.</p> <p>JEN has used a combination of its 2014 (AMI) meter data and its 2009 distribution Substation Utilisation Profiling System (SUPS) model to determine the distribution substation loading modelling for the 2010 and 2014 years.</p> <p>JEN has recognised that the Advanced Metering Infrastructure (AMI) data will be more accurate than its 2009 distribution Substation Utilisation Profiling System (SUPS) model. As such JEN has relied on the 2014 AMI meter data where possible to back derive the 2010 loading. This will allow consistent data to be used in the augex model.</p> <p>Note that since JEN had not finished its AMI meter rollout program prior to summer 2014 some estimation had to be made to first derive the 2014 distribution substation MD data using the 2009 SUPS model. The rules used to derive the 2014 actual MD data were:</p>	<p>adequate for use in the augex model.</p> <p>In the absence of actual data JEN has assumed that the methodology used to estimate its 2010 and 2014 loading and ratings data are sufficient for use in the augex model. It should be noted that a significant amount of estimation has been used to derive a full set of consistent data for both the 2010 and 2014 years.</p> <p>JEN has assumed in this table and in its augex model calibration that half of the forecast system growth is attributable to the current distribution substation population, with the rest being due to new load on new customer initiated substations to be installed.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<ul style="list-style-type: none"> • For subs with 90% of customers with AMI meters, the MD reading from the AMI meters was used. To estimate the MD for 100% of customers the MD was escalated on a pro rata basis. • The metered data was converted from kW to kVA using a pf of 0.8. • For substations with less than 90% of customers with AMI meters use the MD from the SUPS model was used. If JEN had added a substation through its augmentation program which offloaded a substation between 2009 and 2014, the SUPS model MD was reduced by 50%. • For new substations not in SUPS the utilisation was assumed to be 25% (the load will likely only be partial for new substations). • To calculate the cyclic rating, 117% of nameplate was used for pole type substations and 100% or nameplate was used for kiosks/ground and indoor type substations. The nameplate rating was extracted from GIS. • The distribution substation total was reconciled to the 2014 system MD. 	

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>To ensure consistency the 2010 MD data was derived using the 2014 data for use in the augex model:</p> <ul style="list-style-type: none"> • The new substations installed after 2010 were removed. • For substations that were offloaded by a substation added due to augmentation between 2010 and 2014, the 2014 AMI demand was increased by 200%. • For substations upgraded between 2010 and 2014 the SUPS model nameplate rating was used with the above assumptions applied to calculate the cyclic rating. • The distribution substation total was reconciled to the 2010 system MD. <p>The SUPS model methodology can be found in the 2009 "Distribution Substation and LV Circuit MD and Budget Forecast Methodology" procedure.</p> <p>The MD data was then corrected to 50% POE using a system weather correction factor derived in previous category analysis RIN's section "5.4 MD – Network Level".</p>	

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					The forecast % p.a. growth was estimated as half of the system level 50% POE growth across the forecast period.	
TABLE 2.4.5	AUGEX MODEL INPUTS - NETWORK SEGMENT DATA	Estimated – Historical Variables Forecast – Forecast Variables	The historical augex model average unit cost and capacity factor variables are calculated using the estimated historical capex and capacity added as split in table 2.4.6. The utilisation threshold and standard deviation have been derived using the augex model itself.	The historical and forecast augex model average unit cost and capacity factor variables are calculated using the estimated data used to populate the capex and capacity added as split in table 2.4.6. The utilisation threshold and standard deviation have been produced from the calibration of the augex model to match JEN's capacity added.	<u>Average unit cost \$/MVA</u> The historical average unit cost in \$/MVA for each segment was derived by taking the network initiated capex for years 2011 -14 and dividing it by the network initiated capacity added from 2010 -14. Note use of 2011-14 capex rather than the 2010-14 capex as requested in table 2.4.6 aligns the most recent 4 years of expenditure with the 4 years of MD/capacity change as requested in tables 2.4.1-2.4.4. The historical network initiated capacity added was derived by examining the capacity change between 2010 and 2014 and determining the cause (network initiated, customer initiated, residual/un-modelled). For HV feeders JEN has only used capacity added where the trunk feeder capacity changes in line with table 2.4.2.	JEN has not used customer initiated capex, or customer initiated or residual capacity added in table 2.4.5 or to run the Augex model since they are not directly dependent on the utilisation of the asset. The AER has not defined historical and forecast years in this table. JEN has taken historical to be years 2011-14 for capex (to align with the 2010-14 MD change). It has taken forecast to be the years 2015-20 for capex (to align with the 2014-20 MD/capacity change). Given JEN's low proportion of short rural JEN has effectively been required to combine its short rural/urban population when calibrating the augex model. Subsequently the utilisation threshold parameters are the same for the short rural and urban

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>The historical distribution substation network initiated capacity added was determined by determining the average net capacity added per sub added/upgraded in 2014 and applying this to the number of subs upgraded/added from 2011-14 as per previous category analysis RIN's.</p> <p>The forecast average unit cost in \$/MVA for each segment was derived by taking the network initiated capex for years 2015 -20 and dividing it by the network initiated capacity added from 2014 -20 as in table 2.4.6.</p> <p><u>Capacity Factor</u></p> <p>To calculate the capacity factor JEN has first determined the network initiated capacity added over the 2010-14 and 2014-20 periods as above. The capacity requiring augmentation was then calculated as the corresponding amount of capacity that was augmented. The capacity factor is then capacity added divided by the capacity requiring augmentation.</p> <p>For HV feeders JEN has only</p>	<p>categories in this table. Similarly as explained in 2.4.6 below the \$/MVA and capacity factors used were the same.</p> <p>As explained in 2.4.3 above for the forecast period JEN has split its zone-substations into growth and no growth categories in the forecast period only. Subsequently under network ID 2 ("zone substations –all (historical)") the forecast has been left blank and the historical has been left blank under network ID 3 ("zone substations – Forecast growth") and 4 ("zone substations Forecast no growth").</p> <p>It is assumed that JEN's methodology to calculate the variables is in line with the AER's expectations of how this should be calculated.</p> <p>For zone-substations the substation normal cyclic rating was used to determine the capacity added and capacity requiring augmentation.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>used capacity added and capacity requiring augmentation where the trunk feeder capacity changes in line with table 2.4.2.</p> <p>The distribution substation capacity factor for both historical and future was determined using the average capacity added and capacity requiring augmentation per sub added/upgraded in 2014.</p> <p><u>Utilisation Threshold and Standard Deviation</u></p> <p>The utilisation threshold was determined by calibration of the augex model to match the capacity added for each period.</p> <p>For the historical period since net growth was very low or negative an adjustment factor was first applied to the growth to enable the model to run and calibrate the utilisation threshold. Once calibrated this adjustment factor was then deducted from the utilisation threshold provided in this table. To calibrate the utilisation threshold in this table JEN has adjusted the growth to 1.5% p.a. for each segment.</p>	<p>The standard deviation was assumed to be the square root of the utilisation threshold for both periods in line with a normal distribution.</p> <p>It is assumed that the 2014 sample of distribution substation augmentations provides an adequate representation of the forecast capacity added and capacity requiring augmentation.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>For the forecast period JEN is forecasting sufficient growth (as per table 2.4.1-2.4.4) to enable the model to run and calibrate the utilisation threshold applied. As mentioned in table 2.4.3 for the forecast JEN has split its zone-substations in the forecast period into 2 separate categories. The 2 categories are the zone-substations that had negative growth and those that had positive growth. This was done to capture the differences in utilisation profiles for JEN's growth and no growth regions across its network.</p> <p>The standard deviation was assumed to be the square root of the utilisation threshold for both periods in line with a normal distribution.</p>	
TABLE 2.4.6	CAPEX AND NET CAPACITY ADDED BY SEGMENT GROUP	<p>Estimated – Historical capex</p> <p>Forecast – Future capex and net capacity added</p>	<p>The historical capex is estimated since the direct cost is based on direct expenditure data provided in previous RINs which was categorised as estimated due to the removal of embedded overheads prior to 2013. JEN has does not split its</p>	<p>To determine the required capex split JEN has used the capex data which was used to derive RIN category analysis sections "2.3 Augex Project Data" and "2.5 Connections" over the 2010-20 period.</p> <p>The historical capacity added data was derived from data provided in table 2.4.1.-</p>	<p><u>NSP initiated and capacity-related augmentation - Capex</u></p> <p>The NSP initiated and capacity-related augmentation historical expenditure was calculated by re-cutting data previously used to determine RIN category analysis sections "2.3 Augex Project Data" table 2.3.4. The future data used</p>	<p><u>NSP initiated and capacity-related augmentation - Capex</u></p> <p>It should be noted as in table 2.4.5 above, given JEN's low proportion of short rural JEN has effectively been required to combine its short rural/urban population when calibrating the utilisation</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
			expenditure into the categories requested and has had to make some assumptions.	2.4.5. The forecast capacity added data was derived from the scope of works of JEN's forecast projects.	<p>the capex in the JEN EDPR capex forecast model. JEN has defined the below rules to re-cut the augex capex into the required categories:</p> <ul style="list-style-type: none"> • Non capacity driven/related works put in unmodelled • Distribution substation and LV feeder projects were grouped • Some projects were re-categorised based on the project driver (i.e. a capacitor bank in a zone-substation where the driver was an overloaded subtransmission line). <p>The capex was also required to split the capex into rural and short urban for HV feeders and distribution substations/LV feeder. This has been performed by splitting the capex using the % urban/short rural split of capacity added over the 2010-14 period for historical capex and the 15-20 period for future capex.</p> <p>The historical capex was escalated to real 2015 dollars using the relevant inflation indices.</p> <p><u>Customer initiated and capacity-</u></p>	<p>thresholds in the model. The estimated splits into short rural/urban are reported in this table as requested but were not used in calculating separate \$/MVA or capacity factors.</p> <p>To provide the data split in this table it was assumed that the split of capacity added by short rural/urban is an adequate representation of the split of capex into the required categories. Effectively this also means that JEN has assumed the short rural/urban categories have the same \$/MVA in running the augex model.</p> <p>It is assumed that the rules used to group expenditure are adequate.</p> <p><u>Customer initiated and capacity-related augmentation – Capex</u></p> <p>JEN has not used customer initiated capex or capacity added in table 2.4.5 or to run the Augex model since they are not directly dependent on</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p><u>related augmentation – Capex</u></p> <p>The customer initiated and capacity-related augmentation historical expenditure was calculated by re-cutting category analysis RIN sections “2.5 connections” tables 2.5.1 and 2.5.2. Similarly the future data was derived utilising tables 2.5.1 and 2.5.2 of this RIN.</p> <p>The below rules to re-cut the connections capex into the required categories:</p> <ul style="list-style-type: none"> • Subtransmission expenditure was obtained from Table 2.5.2 category “complex connection sub-transmission” • HV feeder expenditure was obtained by summing the Augmentation HV expenditure categories in table 2.5.1 • Distribution substation and LV feeder expenditure was obtained by summing the “Augmentation LV” and “distribution substation installed total spend” categories in table 2.5.1. <p>The capex was also required to split the capex into rural and short urban for HV feeders and distribution substations/LV feeder. JEN has performed this capex</p>	<p>the utilisation of the asset. As such all of the expenditure could have been assigned to unmodelled as it should not be used in the augex model. Regardless JEN has attempted to split the data into the required categories.</p> <p>It is assumed that JEN had no zone-substation augmentation historically and is not forecasting any in its capex model in the forecast period.</p> <p>It was assumed that the % total network capacity split by short rural/urban is a good representation of the split of customer initiated capex into the required short rural/urban categories.</p> <p><u>NSP initiated and capacity-related augmentation – Capacity Added</u></p> <p>Note since JEN already provided the 2014 ratings in table 2.4.1-2.4.4 it is assumed that the requested capacity added over the 2014-15 period is only the capacity to</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>split using the % of total capacity of its HV feeders and distribution substations that are short rural and urban.</p> <p>The historical capex was escalated to real 2015 dollars using the relevant inflation indices.</p> <p><u>NSP initiated and capacity-related augmentation – Capacity Added</u></p> <p>To forecast the capacity added from 2014 to 2020 JEN has used its project list in the EDPR capex model and determined from the scope of works how much capacity is to be added to each segment.</p> <p>For HV feeders JEN has only reported capacity added where the trunk feeder capacity will change in line with table 2.4.2. JEN has split the short rural/urban capacity added based on the current classification of the feeder to be augmented.</p> <p>For distribution substations the capacity to be added was determined by determining the average net capacity added per sub added/upgraded in 2014 and applying this to the number of subs forecast to be</p>	<p>be added in 2015.</p> <p>It is assumed that the 2014 sample of distribution substation augmentations provides an adequate representation of the forecast capacity added per sub added/upgraded.</p> <p>For subtransmission lines no capacity was added for projects where a new zone-substations was cut in and out of an existing line.</p> <p><u>Customer initiated and capacity-related augmentation – capacity added</u></p> <p>JEN has not used customer initiated capex or capacity added in table 2.4.5 or to run the Augex model since they are not directly dependent on the utilisation of the asset. As such all of the capacity added could have been assigned to unmodelled or residual as it should not be used in the augex model. Regardless JEN has attempted to split the data into the required</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>upgraded/added from 2015-20 in table 2.3.3.</p> <p><u>Customer initiated and capacity-related augmentation – capacity added</u></p> <p>JEN has determined the capacity added for its subtransmission line projects from the scope of works for the 2 forecast customer initiated projects subtransmission line projects in its EDPR capex model.</p> <p>For HV feeders the capacity added has been forecast using the unit rate of total capacity added over the 2010-14 period, applied to the forecast short rural/urban capex.</p> <p>For distribution substations the capacity added has been forecast using the nameplate MVA added in table 2.5.1. In table 2.5.1 the MVA added was gross. This was converted to net as in table 3.5.2.1. This was then converted to cyclic rating capacity added in line with table 2.4.4 using the average nameplate to cyclic rating factor of JEN substations in 2014 (~1.07). Similar to the capex the short rural/urban split was determined based on the % of distribution substation capacity</p>	<p>categories.</p> <p>It is assumed that JEN had no zone-substation augmentation historically and is not forecasting any in its capex model in the forecast period.</p> <p>In addition to the assumptions in table 2.5.1 JEN assumes that the distribution substations network cyclic rating factor and current short rural/urban capacity split is representative of capacity that will be added over the 2015-20 period.</p>

Base information		Data Type		Population approach		
Table number	Table Name	Actual Historical and/or Estimated Historical, Forecast	Reasons For estimation	Source	Methodology	Assumptions
					<p>that is currently short rural and urban.</p> <p><u>Net Capacity Added – In total for all purposes</u></p> <p>JEN has determined the net capacity added by combining the network initiated, customer initiated, and residual capacity added sections. The residual capacity added section was determined by capacity added not in either of the other two categories. These are due to projects that should not be modelled in the augex model (i.e. capacity that may be added from a replacement driven project or other non MD related reason).</p>
