

Application Notice

Proposed New Large Network Asset – Gold Coast and Tweed Areas

Joint Report by Powerlink Queensland & ENERGEX Limited
19 April 2004

Disclaimer

While care was taken in preparation of the information in this paper, and it is provided in good faith, Powerlink and ENERGEX accept no responsibility or liability for any loss or damage that may be incurred by any person acting in reliance on this information or assumptions drawn from it. This Application Notice has been prepared for the purpose of inviting information, comment and discussion from interested parties. The document has been prepared using information provided by a number of third parties. It contains assumptions regarding, among other things, economic growth and load forecasts which may or may not prove to be correct. All information and underlying assumptions should be independently verified to the extent possible before assessing any investment proposals.

DOCUMENT PURPOSE

For the benefit of those not familiar with the National Electricity Code (NEC) and the National Electricity Market (NEM), Powerlink and ENERGEX offer the following clarifications on the purpose and intent of this document:

- 1. The document is produced in accordance with the NEC, which requires Powerlink and ENERGEX, as part of forward planning, to identify foreseeable FUTURE supply requirements in its network, <u>well in advance</u> of them becoming an operational problem.
- 2. The NEC requires Powerlink and ENERGEX to identify, evaluate and compare both network and non-network solutions to determine which can overcome the future supply requirements at the <u>lowest cost to electricity consumers</u>. This document contains the results of this evaluation in accordance with NEC requirements.
- 3. The purpose of this document is to recommend a solution, in time for it to be implemented to address future supply requirements, and allow input by industry participants and other interested parties. While longer-term requirements are considered, only works required to be completed by 2006 are recommended in this document.

What the document does NOT mean:

- A. It does NOT mean that the lights are about to go out. The identified supply requirements are expected to arise some <u>years into the future</u>, assuming that demand for electricity continues to grow. There is enough time between now and then to implement a solution.
- B. It does NOT mean that Powerlink and ENERGEX have been surprised, or that anything is "out of the ordinary". On the contrary, it is part of the normal, routine planning processes in the NEM.

EXECUTIVE SUMMARY

Introduction

Electricity demand in the Gold Coast/Tweed area has grown strongly in recent years due to population growth, significant housing and commercial development and other factors, and growth is forecast to continue into the future. Powerlink Queensland, ENERGEX and Country Energy recognise the importance of ensuring a reliable supply to their customers in this area can be maintained, and of ensuring the electricity supply system can cater for future growth.

This document has been prepared as part of a standard National Electricity Code process for the approval of new electricity network developments. It contains recommendations for works to meet reliability of electricity supply obligations in 2005 and 2006. These recommendations have been developed following joint planning activities between Powerlink and ENERGEX, and their NSW counterparts, TransGrid and Country Energy.

Future Supply Requirements

Powerlink, ENERGEX, TransGrid and Country Energy, have identified future supply requirements in the Queensland electricity network supplying the Gold Coast/Tweed zone, and in the New South Wales electricity network supplying the far north coast of New South Wales. This document deals with the "Gold Coast/Tweed zone", which includes the Gold Coast area (south of Cades County) in south-east Queensland and the Tweed Shire in northern New South Wales.

The Gold Coast/Tweed zone is primarily supplied by two single circuit 275kV transmission lines between Swanbank substation near Ipswich and Mudgeeraba/Molendinar substations on the Gold Coast. The existing network has adequate capacity for the present needs of the area. However, with load growth forecast for the Gold Coast/Tweed zone, there will be a need to augment the existing electricity system.

Planning studies have identified that, during periods of peak load, the capability of the existing network to supply the Gold Coast/Tweed zone will be exceeded during a single contingency by late 2005. Interruptions to power supply during single network contingencies are not consistent with the reliability standards which Powerlink, ENERGEX and Country Energy must meet. Proposals in this document will prevent such interruptions during critical contingencies, and are therefore 'reliability augmentations' as defined in the National Electricity Code.

The future supply requirements forecast for the NSW transmission and distribution network supplying the Far North Coast area of NSW from Armidale have been considered during joint planning between Powerlink, ENERGEX, TransGrid and Country Energy. Potential solutions to address the northern NSW supply requirements have been taken into account in the analysis of actions to maintain a reliable supply to the Gold Coast/Tweed zone.

Options Considered

Powerlink and ENERGEX carried out a consultation process to identify feasible options, including non-network options (eg - involving demand side management initiatives, market network service providers or local generation) to address the Gold Coast/Tweed zone requirements. Four submissions regarding alternative options were received from ENERGEX Retail, TransEnergie Australia, Delta Electricity and Stanwell Corporation. Powerlink had discussions with these organisations to understand the potential options raised in the submissions. The only viable option identified in those discussions was the potential use of the DirectLink unregulated interconnector to provide network support to augment supply to the Gold Coast/Tweed zone.

In addition to the consultation process, alternative network augmentation options to address the future supply requirements for the Gold Coast/Tweed area were considered. Joint planning studies were carried out between Powerlink, ENERGEX, TransGrid and Country Energy to evaluate these alternatives, and consider the impacts of modelled projects to address the forecast requirements in northern New South Wales.

A total of eight options were evaluated in detail to compare the Net Present Value (NPV) of the costs to market participants, in accordance with the Regulatory Test. The augmentation options to address the Gold Coast/Tweed zone requirements in 2005 and 2006 include:

Option 1	110kV Augmentation Beenleigh – Molendinar in late 2005
Option 2	275kV Augmentation Greenbank - Maudsland in late 2005
Option 3	Network support from DirectLink for the summer of 2005/06, followed by 275kV
	augmentation Greenbank - Maudsland in late 2006
Option 4	"Double tee" connection Maudsland – Molendinar in late 2005, followed by 275kV
	augmentation Greenbank - Maudsland in late 2006

For each of these four alternatives to satisfy Gold Coast/Tweed zone needs, a variation to examine the impact of modelled projects to address northern NSW requirements was considered as follows:

Options 1A to 4A: Network support from 2006 onwards, OR;

Options 1B to 4B: Construction of Dumaresq – Lismore 330kV Line in 2006.

Evaluation and Conclusion

The ACCC Regulatory Test requires that, for reliability augmentations, the recommended option represent the lowest Net Present Value cost under the majority of market development scenarios considered. To allow comparison of options on an equivalent basis, the economic analysis was carried out over fifteen years, and included consideration of anticipated/modelled projects that are expected to be required in this period to meet forecast growth in electricity demand in the Gold Coast/Tweed zone. Market development scenarios and other analytical techniques were used to check the sensitivity of the outcome to changes in these assumptions.

A draft recommendation to meet future network supply requirements has been developed, following joint planning between the relevant transmission and distribution network service providers in both states. In accordance with the National Electricity Code, Powerlink and ENERGEX have published this draft recommendation as an "Application Notice for a New Large Network Asset". The economic analysis identified that proposed augmentation Option 3A - "Network Support from DirectLink in Summer 2005/06, followed by 275kV Augmentation Greenbank-Maudsland in 2006" - is the least-cost solution over the fifteen year period of analysis. Sensitivity analysis showed the results of the financial analysis to be robust under a range of assumptions.

Consequently, this Application Notice contains a draft recommendation to implement this option, subject to finalising a satisfactory network support agreement with the owners of DirectLink, to address the future supply requirements of the Gold Coast/Tweed zone in 2005 and 2006. The draft recommendation is for:

- Provision of network support to the Gold Coast/Tweed zone by DirectLink for the summer of 2005/06 at an estimated total cost of \$2.7M
- Establishment of a 275kV switchyard at Greenbank, and construction of a 275kV transmission line between Greenbank and Maudsland by late 2006. Construction of this proposed augmentation, estimated to cost \$48.9M, is expected to begin in late 2004, for commissioning by late 2006.

Powerlink and ENERGEX invite submissions on this Application Notice from Code Participants and interested parties. The closing date for submissions is Friday 4th June, 2004.

1. INTRODUCTION

Queensland's Gold Coast and the far northern areas of NSW have seen rapid population growth, and significant housing and commercial development in recent years. Continued growth in electricity demand in these areas is anticipated as a result of these and other factors.

The area supplied from the Queensland electricity network includes the Gold Coast area (south of Cades County) in southeast Queensland and the Tweed Shire in northern New South Wales. As part of their commitment to maintaining a reliable supply to their customers in the area, Powerlink, ENERGEX and Country Energy have determined that action is now required to meet the electricity supply requirements in the Gold Coast/Tweed zone in 2005 and 2006.

This document has been prepared as part of a standard National Electricity Code (NEC) process for the approval of new large electricity network assets. Where a network service provider proposes to establish a new large network asset, it is required to issue an 'Application Notice' under clause 5.6.6 of the National Electricity Code. This 'Application Notice' must contain information regarding:

- the reasons the augmentation is required, including, if relevant, why it is considered a 'reliability augmentation' as defined in the Code;
- feasible options available to address the future supply requirements, including non-network alternatives and options involving other transmission and distribution networks;
- the recommended solution, including the timetable for implementation; and
- why the solution satisfies the Regulatory Test prescribed by the Australian Competition and Consumer Commission (ACCC).

The focus of this Application Notice is ensuring a reliable electricity supply to the Gold Coast and Tweed areas can be maintained. However, the NEC requires the consideration of options involving other transmission and distribution networks (ie – network ownership and state boundaries are not barriers to determining a feasible option). In the case of the Gold Coast/Tweed zone, this requires Powerlink and ENERGEX to examine options for supply from New South Wales as well as from Queensland. For this reason, Powerlink and ENERGEX have carried out joint planning with their counterparts in New South Wales - TransGrid and Country Energy. This joint planning included consideration of action that may be necessary to address future electricity supply requirements in the northern New South Wales area supplied from Armidale via TransGrid and Country Energy's networks.

This document contains a draft recommendation for action to be taken by late 2005 and late 2006 to meet reliability of electricity supply obligations. This draft recommendation is based on:

- the assessment that action is now required to maintain a reliable power supply in the Gold Coast/Tweed area during single network contingencies from late 2005 onwards;
- the consultation undertaken by Powerlink and ENERGEX to identify potential solutions to address these future supply requirements;
- the interrelationship between the forecast supply requirements in the Gold Coast/Tweed area and in the far north coast of New South Wales area supplied from Armidale in NSW; and
- analysis of feasible options in accordance with the Regulatory Test prescribed by the Australian Competition and Consumer Commission (ACCC).

The recommended solution maximises the net economic benefits to participants in the National Electricity Market while meeting the reliability standards in the National Electricity Code. These economic benefits arise from maintaining a reliable power supply during single network contingencies at the least cost to the market and therefore to end-use customers.

2. REASONS AUGMENTATION IS REQUIRED

2.1 Supply to the Gold Coast/Tweed Zone

Powerlink and ENERGEX have identified future supply requirements in the electricity network supplying the Gold Coast/Tweed area from Queensland.

The geographic area referred to in this 'Application Notice' as the Gold Coast/Tweed zone spans the border between the states of New South Wales and Queensland, and is shown on the map below. It is defined as the Gold Coast area of south-east Queensland (south of Cades County) to Coolangatta, together with the Tweed Shire in northern New South Wales. This includes the entire Gold Coast/Tweed tourism, commercial and residential area.

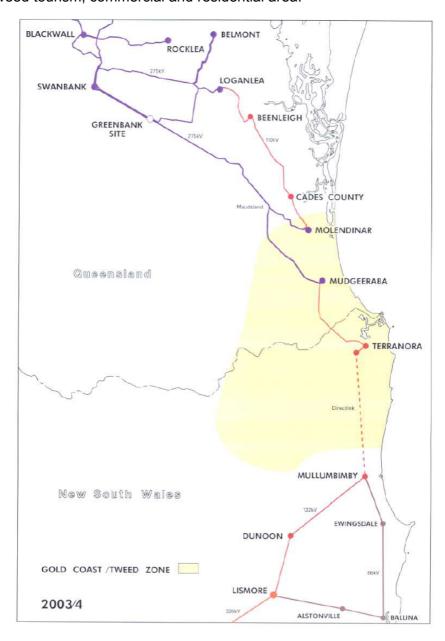

Figure 1: Electicity supply system to Gold Coast/Tweed Area

Customers in the Gold Coast/Tweed zone receive their electricity supply from local distributors in each state, namely ENERGEX in Queensland and Country Energy in New South Wales.

The majority of the electricity used in the area is produced at Queensland power stations. It is transferred to the Gold Coast/Tweed zone via Powerlink's 275kV transmission network, with support from the ENERGEX 110kV network. The primary supply to the Gold Coast/Tweed zone is via two single circuit 275kV transmission lines from Swanbank (near Ipswich west of Brisbane) to Mudgeeraba (on the southern end of the Gold Coast)¹. Under typical conditions, these high voltage transmission circuits deliver more than 95% of the power used in the area.

A secondary supply path is available from Powerlink's 275kV substations at Belmont and Loganlea to the Gold Coast area via Beenleigh. This path consists of a single circuit 110kV line between Beenleigh and Cades County, and another single circuit 110kV line from Cades County to Molendinar². This 110kV network typically supplies power to areas to the north of the Gold Coast/Tweed zone (only as far south as Cades County). That is, power is transferred south from Beenleigh to Cades County and north from Molendinar to Cades County. However, during a contingency resulting in an outage of one of the 275kV circuits between Swanbank and the Gold Coast, power on the 110kV circuits between Cades County and Molendinar can flow southwards to provide back-up supply to the Gold Coast/Tweed zone.

Additional power supply to the Gold Coast/Tweed zone can be provided by the DirectLink unregulated interconnector, which has the capacity to transmit up to 168MW³ into the area from power stations in New South Wales. DirectLink is a "market network service provider" connecting the Queensland and New South Wales electricity systems. As such, its operations depend on market conditions. Using DirectLink to support the Queensland network would require a network support agreement between the owners of DirectLink and Powerlink.

Future works in the Gold Coast/Tweed zone are also underway. Powerlink is installing a shunt capacitor bank at Molendinar to assist with managing voltage stability in South East Queensland. This is scheduled for commissioning in October 2004. ENERGEX is also establishing the Coomera 110/33kV substation in 2005, which would transfer a significant portion of the 33kV load currently supplied from Molendinar to the area supplied from Loganlea. The network including these future developments is shown in Figure 2.

2.2 Ownership

There are four regulated electricity network owners relevant to supply to the Gold Coast/Tweed zone:

- Powerlink Queensland is the owner and operator of the Queensland high voltage transmission grid, including the 275kV transmission network supplying the Gold Coast/Tweed zone.
- ENERGEX owns and operates the electricity distribution network in south-east Queensland, including the Gold Coast area.
- Country Energy owns and operates the electricity distribution network in northern New South Wales, including the Tweed area.
- TransGrid is the owner and operator of the New South Wales high voltage transmission network, which provides supply to distribution networks in NSW, excluding the Tweed area.

_

¹ One of which has a tee connection to Molendinar. Powerlink recently completed construction of this 275kV tee connection to establish a second Gold Coast 275/110kV injection point at Molendinar. This project consisted of a 12.5km transmission line connecting into one of the existing Swanbank-Mudgeeraba 275kV circuits at Maudsland.

² Both lines are owned by ENERGEX

³ Refer discussion regarding DirectLink capability in section 3.4.

The DirectLink market service is owned by a joint venture that includes HQI Australia Pty Ltd, a subsidiary of Hydro Quebec International, and EMMLink Pty Ltd, a subsidiary of Country Energy. Power station ownership in New South Wales and Queensland is in the hands of various private companies and government-owned corporations.

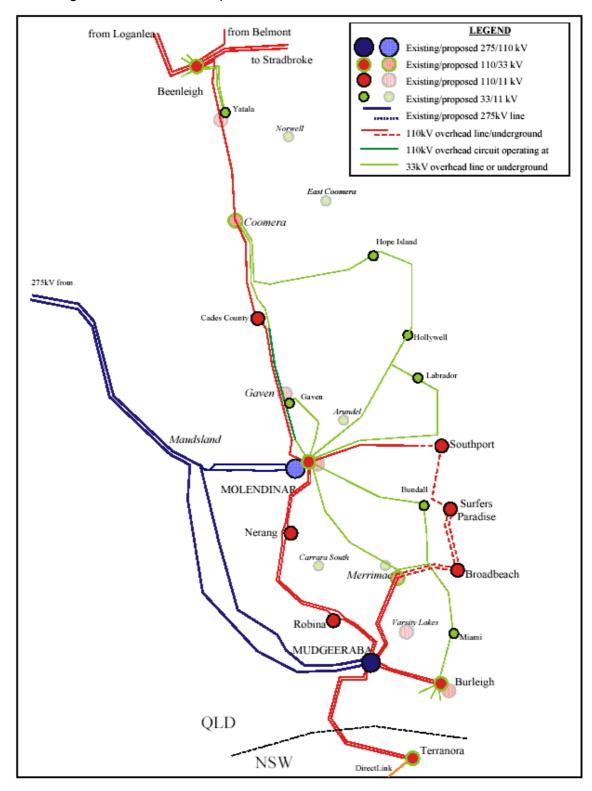

Figure 2: Gold Coast/Tweed 110kV and 275kV Supply

2.3 Future Supply Issues for Gold Coast/Tweed Zone

Powerlink and ENERGEX have identified that action is now required to maintain a reliable power supply to the Gold Coast/Tweed zone from late 2005 onwards, and to cater for future growth in the region.

Planning studies have determined that during periods of peak summer demand, the capability of the existing network to supply the Gold Coast/Tweed zone will be exceeded during a single 275kV contingency by the summer of 2005/06⁴⁵⁶. For supply to the Gold Coast/Tweed zone, the most critical contingency occurs when the 275kV Swanbank to Mudgeeraba circuit with the Maudsland to Molendinar tee connection is out of service. This circuit provides 275kV supply to both Molendinar and Mudgeeraba. Following an outage of the teed circuit from late 2005 onwards, unstable voltages are forecast to occur, and the 110kV lines between Beenleigh and Coomera would become overloaded.

This would require interruptions to power supply during single network contingencies, which are not consistent with reliability standards which Powerlink and ENERGEX must meet. Action is therefore required by late 2005 to prevent voltage collapse and ensure network overloads do not occur during a 275kV network contingency.

The conclusion that action must be taken by late 2005 is based on forecast demand growth averaging a predicted 3.6% per annum for the next 10 years, with an intense growth period of 6% p.a. over the next three year period (approximately 25 – 40MW per year). Due to heavy use of air conditioning and the distance from major power generation sources, the Gold Coast/Tweed zone also has a high reactive power demand⁷ with a consequent impact on voltage stability.

Solutions to the future supply requirements identified in 2005 and 2006 may accommodate further load growth in the Gold Coast/Tweed zone beyond this period. Depending on action taken, additional supply requirements may occur by the summer of 2007/08. By that time, the electricity demand in the Gold Coast/Tweed zone will have grown to the extent that the thermal capability of the existing 275kV lines supplying the area from Swanbank will be exceeded during a single network contingency⁸.

Analysis to support these conclusions, including load forecasts and relevant assumptions, was published in the previous document "Request for Information – Emerging Transmission Network Limitations: Electricity Transfer to the Gold Coast and Tweed Area." 9

Consistent with the National Electricity Code, Powerlink's transmission authority and Connection Agreement requirements, Powerlink is required to plan its network supplying ENERGEX and

_

⁴ The transfer limit is influenced by the pattern of generation in southeast Queensland. The base case assumed in this modelling is that Swanbank E power station is running at 320 MW, three Swanbank B units are running at 100MW each and two Wivenhoe units are running, one generating 100MW and one running as a synchronous condenser. These assumptions are based on a typical market dispatch observed in summer peak periods.

⁵ Powerlink and ENERGEX have agreed some short term operational strategies to manage the network prior to the summer of 2005/06 should the demand require power flows which approach the transfer limit of the network. Such operational strategies are only a short-term measure, and from the summer of 2005/06 onwards, action to increase the supply capacity to the Gold Coast/Tweed zone is required.

⁶ The output of embedded generation continues to be included as a reduction in forecast peak demand and therefore has already been accounted for.

⁷ A technical characteristic of electricity demand in an alternating current system that increases the requirement for voltage support.

⁸ In the absence of other action, when one 275kV circuit is out of service, the remaining 275kV circuit and the 110kV lines between Beenleigh and Molendinar will become overloaded.

⁹ Published 22 August 2003 - refer Powerlink's website: www.powerlink.com.au

Country Energy so that the reliability and power quality standards of Schedule 5.1 of the Code can be met during the worst single credible network fault or contingency (N-1 conditions) unless otherwise agreed with affected participants. Relevant obligations are outlined below:

- i Powerlink must "ensure as far as technically and economically practicable that the transmission grid is operated with enough capacity (and if necessary, augmented or extended to provide enough capacity) to provide network services to persons authorised to connect to the grid or take electricity from the grid" (Electricity Act 1994, S34.2).
- ii "The transmission entity must plan and develop its transmission grid in accordance with good electricity industry practice such that... the power transfer available through the power system will be adequate to supply the forecast peak demand during the most critical single network element outage" (Transmission Authority No T01/98, S6.2).
- The Connection Agreement between Powerlink and ENERGEX includes obligations regarding the reliability of supply as required under clause 5.1.2.2 of the Code. Capacity is required to be provided to the Gold Coast area such that forecast peak demand can be supplied with the most critical element out of service, without the necessity to interrupt customer load ie N-1. Country Energy has confirmed that it requires Powerlink to provide the same level of supply reliability to its customers in the Tweed area.

If no action is taken, interruptions to customer supply will need to occur throughout the Gold Coast/ Tweed zone during peak summer periods from October 2005, should an outage occur on a 275kV circuit between Swanbank and Mudgeeraba/Molendinar. This is not consistent with reliability of electricity supply obligations. Powerlink, ENERGEX and Country Energy therefore consider action to address the future supply requirements in the Gold Coast/Tweed zone to be a 'reliability augmentation', as defined in the National Electricity Code¹⁰.

Conclusion on Gold Coast Future Supply Requirement

The discussion above demonstrates the need for action to reinforce supply to the Gold Coast/Tweed zone by late 2005 to avoid voltage instability and line overloads. Because this reinforcement is necessitated solely by the inability to meet reliability of supply obligations, it is a 'reliability augmentation' as defined in the Code.

2.4 Supply to the Far North Coast of New South Wales

TransGrid and Country Energy have identified future supply requirements to the Far North Coast area of New South Wales from Coffs Harbour north to Byron Bay and west to Tenterfield. The relevant area does not include the Tweed Shire, which is normally supplied from the Queensland electricity network.

Because of the interconnected nature of electricity networks, these future NSW supply requirements need to be considered in assessment of action to address future supply requirements in the Gold Coast/Tweed zone. For this reason, Powerlink and ENERGEX carried out joint planning with their NSW counterparts, TransGrid and Country Energy.

¹⁰ A transmission network augmentation that is necessitated solely by inability to meet the minimum network performance requirements set out in schedule 5.1 or in relevant legislation, regulations or any statutory instrument of a participating jurisdiction.

In brief, the Far North Coast of NSW is supplied by a single 330kV transmission line that connects 330/132kV substations at Armidale and Lismore. A 132kV transmission network operates in parallel with this 330kV line. As noted earlier, the DirectLink 'market network service provider' also provides a connection between Queensland and New South Wales.

The capacity of the NSW system to maintain a reliable supply to the Far North Coast area is being approached during a single network contingency on the Armidale – Lismore 330kV line. Readers are referred to a document published by TransGrid and Country Energy in August 2003¹¹ for further information regarding the future network requirements, load characteristics and forecast growth in the subject area.

Joint planning studies considered inter-relationships between supply to the Gold Coast/Tweed zone and the Far North Coast area of NSW, such as the potential use of DirectLink to provide network support to either Queensland or New South Wales. Modelled projects to address the future supply requirements in northern New South Wales from mid 2006 have been taken into account in evaluation of actions to maintain a reliable supply to the Gold Coast/Tweed zone.

TransGrid and Country Energy received one submission from TransEnergie Australia to their 'Request for Information' document issued in August 2003. An Application Notice regarding supply to the Far North Coast of NSW will be issued in the future, when this is required to meet TransGrid and Country Energy's reliability of supply obligations.

Conclusion on New South Wales Far North Coast Limitation

Action may be required in the future to reinforce supply to the NSW Far North Coast to maintain satisfactory voltage levels and prevent load-shedding during single contingencies. Modelled projects to address this forecast limitation have been considered in the analysis in this Application Notice. An Application Notice for a proposed augmentation in NSW will be issued in the future, when this is required to meet TransGrid and Country Energy's reliability of supply obligations.

_

3. OPTIONS CONSIDERED

3.1 Identification and Assessment of Options

Powerlink and ENERGEX have undertaken consultation to identify potential solutions to the future supply requirements in the Gold Coast/Tweed zone.

In conjunction with TransGrid and Country Energy, Powerlink and ENERGEX have also:

- Carried out joint planning studies to consider non-network and network options, including supply from NSW via the DirectLink unregulated interconnector. This included load flow analysis and other technical assessment to determine the capability of potential options to supply future customer electricity needs in the Gold Coast/Tweed zone; and
- Modelled potential solutions to the identified future supply requirements in the Far North Coast of NSW to assess the impact on the Queensland supply requirements.

A summary of the consultation and joint planning outcomes, together with an outline of the options and modelled projects considered, are contained in sections 3.2 to 3.5 and in section 4.0. Further details on feasible options to address the future supply requirements in the Gold Coast/Tweed zone are provided in section 5.0, with economic evaluation of options contained in Appendix 2.

3.2 Summary of Consultation and Joint Planning Processes

Powerlink identified in its 2001, 2002 and 2003 Annual Planning Reports¹² an expectation that action would be required in the relatively short-term to address future supply requirements in the Gold Coast/Tweed zone. No information was put forward by industry participants in response to the Annual Planning Reports.

In August 2003, Powerlink and ENERGEX issued a 'Request for Information' – a consultation document providing more detailed information on future supply requirements in the Gold Coast/Tweed zone. That paper was the first step in meeting regulatory requirements related to proposed network augmentations. It sought information from Code Participants and interested parties regarding potential solutions to address the anticipated network requirements.

Only existing and committed projects that will be operational prior to late 2005 may be viable solutions to maintain a reliable electricity supply to the Gold Coast/Tweed zone.

Submissions were received from four parties in response to the Request for Information:

Delta Electricity provided a submission regarding its joint venture with the NSW Sugar Mill Cooperative. Delta advised that it expects the 30MW co-generation power station project at the Condong Sugar Mill in the Tweed area to achieve committed status by late 2003/early 2004. It further advised that its 30MW cogeneration project at the Broadwater Sugar Mill south of Ballina¹⁴ is also expected to become committed in 2004. Delta requested further discussion of the network issues to allow an assessment of the potential for the Condong generating unit to provide network support services. In subsequent discussions with Powerlink, Delta advised that commissioning of the Condong cogeneration project is being targeted for mid 2006. This generation project will therefore not be in service in the required timeframe to address future supply requirements in the Gold Coast/Tweed zone, which will arise from late 2005 onwards. Local generation options are discussed further in section 3.3.2.

¹² Published in July 2001, June 2002 and June 2003 respectively.

¹³ "Request for Information – Emerging Transmission Network Limitations: Electricity Transfer to the Gold Coast and Tweed Area", August 2003.

¹⁴ The Broadwater Sugar Mill is located outside the Gold Coast/Tweed zone.

- Stanwell Corporation, the owner of the 28MW Rocky Point Power Plant located near Yatala, provided a submission advising that Stanwell considered that Rocky Point will not provide any additional relief to the identified supply requirements. Powerlink and ENERGEX agree with Stanwell's assessment. Rocky Point is not considered further in this Application Notice.
- □ ENERGEX Retail (ERPL) responded to the Request for Information by providing confidential details of demand side management initiatives it is pursuing in the Gold Coast area. This is discussed in section 3.3.1.
- □ TransEnergie Australia provided a submission containing details of the capabilities of the DirectLink market network service provider. The submission affirmed that the DirectLink owners are interested to explore a network support agreement with either Powerlink/ENERGEX or TransGrid/Country Energy. Utilising DirectLink for network support to the Gold Coast/Tweed zone is discussed in section 3.4.

During the consultation process, Powerlink also provided information to several other parties regarding the future Gold Coast/Tweed zone supply requirements. No submissions regarding alternative solutions were provided by these parties.

3.3 Non-Network Options

The "Request for Information" paper sought to identify feasible non-network options to be included in the analysis. Powerlink and ENERGEX have considered the submissions to the Request for Information paper and information provided during related discussions regarding potential options to address the future supply requirements.

3.3.1 Demand Side Management

Demand Side Management (DSM) initiatives involve reducing the amount of power that needs to be supplied through the electricity network. This can be achieved through agreements to interrupt customer electricity supply during peak periods, through energy efficiency initiatives or use of alternative fuel sources such as gas.

Powerlink's demand and energy forecasts include all existing and foreseen DSM initiatives incorporated in ENERGEX and Country Energy's load forecast for the Gold Coast/Tweed zone. These initiatives, which include routine hot water switching activities, are therefore already being used to defer augmentations as long as possible.

Information about other demand side initiatives being pursued was put forward by ERPL, on a confidential basis, during the consultation process. At this point in time, such measures are insufficient to defer the requirement for action to maintain a reliable supply to the Gold Coast/Tweed zone from late 2005 onwards. The reason for this is that the total demand able to be offset or reduced by these initiatives amounts to less than one year's load growth in the Gold Coast/Tweed zone. ERPL have also advised this DSM will be initiated on request, and will not normally be operating so as to reduce demand.

While these initiatives are not large enough to provide sufficient capacity to address the supply requirements in the Gold Coast/Tweed zone in 2005 and 2006, Powerlink and ENERGEX are examining their use as additional short-term operational strategies to assist in managing the network when power flows approach the transfer limit of the network.

3.3.2 New Local Generation

No recently committed local generation projects in the Gold Coast/Tweed zone were advised to Powerlink and ENERGEX following publication of the Request for Information.

An allowance for potential cogeneration and renewable energy developments embedded¹⁵ in the distribution network in the relevant area is already included in ENERGEX and Country Energy's forecasts of electricity demand. Generation <u>above</u> the levels allowed would be required if local generation were to reduce demand on the transmission network and defer the need for other forms of action.

Two generation developers contacted Powerlink during the consultation process. One potential local generation development that was in the very early stages of consideration (ie – pre-feasibility studies) was discussed. There were no indications that this generation proposal could be operational by the required timing of late 2005.

The proposed Condong Sugar Mill cogeneration project was raised in the Delta submission. The anticipated capacity of this project (30MW) is not large in terms of the forecast load growth (25-40MW per year) in the Gold Coast/Tweed zone. As noted above, this project is not a viable solution to the present Gold Coast/Tweed zone requirements, as it is not anticipated to be commissioned until mid 2006.

As noted earlier in this Application Notice, the electricity networks in northern NSW and the Gold Coast/Tweed zone are connected by the DirectLink interconnector. Generation proposals may be developed in northern NSW, such as the Broadwater proposal raised in the Delta submission. To meet future supply requirements in the Gold Coast/Tweed zone, these generation proposals would have to be of sufficient capacity to meet local requirements, as well as being able to generate additional power that could be transferred north to the Gold Coast/Tweed zone across DirectLink. Powerlink and ENERGEX are not aware of any well-advanced generation proposals in northern New South Wales that would satisfy these two requirements.

Powerlink and ENERGEX have therefore concluded that there are no additional generation proposals that can be considered as a viable option to reduce the demand on the electricity network supplying the Gold Coast/Tweed area prior to late 2005.

Powerlink and ENERGEX have concluded that there are no viable non-network options to address

Conclusion on Non Network Options

the future supply requirements in the Gold Coast/Tweed zone. Demand side management initiatives are insufficient to offset one year's demand growth in the Gold Coast/Tweed zone. There is no indication that sufficient new local generation could be developed by the required timeframe of late 2005.

ENERGEX LIMITED & POWERLINK QUEENSLAND – APPLICATION NOTICE GOLD COAST AND TWEED AREAS – 19 APRIL 2004

¹⁵ An embedded generator connects directly to the distribution network. Output from such generators therefore reduces the expected energy that the transmission grid is required to deliver. Embedded generators may also reduce the demand the transmission grid is required to deliver, depending on their mode of operation.

3.4 Network Options – DirectLink Unregulated Interconnector

3.4.1 DirectLink Capability

The DirectLink unregulated interconnector between Terranora and Mullumbimby can transfer power in either direction between the Queensland and New South Wales regions. Hence DirectLink has the potential to provide support to the Gold Coast/Tweed zone by transferring electricity from New South Wales. Maximum operation of DirectLink in a northerly direction can supply the load at Terranora and can transfer some power into the Queensland electricity system at Mudgeeraba. These loads would otherwise be supplied from the Queensland network, and therefore DirectLink, when importing into Queensland, reduces the amount of power that needs to be transferred to the Gold Coast/Tweed zone from power stations in Queensland.

DirectLink can also potentially provide support to the Far North Coast area of NSW. The owners of DirectLink have indicated that the DirectLink interconnector is not presently able to provide support to both Queensland and New South Wales at the same time.

Other factors can affect the capability of DirectLink to provide network support to the Gold Coast/Tweed zone in Queensland. The "nominal" 180MW capacity of DirectLink does not equate to the ability to increase the <u>total</u> customer load that can be supplied in the Gold Coast/Tweed zone by 180MW. This is due to a variety of factors associated with DirectLink and the networks to which it is connected, as outlined below.

Losses Across DirectLink

DirectLink has a nominal capacity of 180MW (3 x 60MW modules). After accounting for losses (primarily in the DirectLink converter stations), the maximum amount of electricity that can be transferred across DirectLink to the northern connection point at Terranora in the Tweed area, is 168MW.

Capacity of the networks to which it is connected¹⁶

Northward flow on DirectLink imposes a significant demand on the northern NSW network to which DirectLink is connected. There is sufficient capacity in the northern NSW network *under normal conditions when all elements of the network are in service* to meet the local northern NSW requirements and to allow for the provision of network support by DirectLink for many years¹⁷.

However, if critical lines in the NSW transmission and distribution network are not in service, the capability of DirectLink to flow northwards will be restricted. From DirectLink's northern connection point at Terranora, electricity is transferred to customers in the Gold Coast/Tweed zone via the ENERGEX and Country Energy distribution networks. If any element of the network between Terranora and Mudgeeraba is out of service, this may restrict the amount of electricity that can be transferred north across DirectLink. Under outages of critical lines providing supply to

¹⁶ Only restrictions relevant to import into Queensland to provide support to the Gold Coast/Tweed zone are discussed in this section. Southward flow on DirectLink can also be restricted by the capacity of the Queensland network which supplies the Gold Coast/Tweed area and DirectLink.

¹⁷ The future supply requirements in northern New South Wales are determined based on contingency conditions for which northward flows on DirectLink will be curtailed. The option where DirectLink is utilised to provide network support to the Gold Coast/Tweed zone therefore has no impacts on these future supply requirements in northern NSW.

DirectLink's southern connection point at Mullumbimby in northern NSW¹⁸, northward flow on DirectLink would also have to be reduced or completely curtailed¹⁹.

Impact on Voltage Stability

As noted above, potential power transfers of up to 168MW into Queensland across DirectLink are technically possible – assuming the entire northern NSW network and the Terranora – Mudgeeraba lines are in service.

However, the capability of DirectLink to provide a viable solution to the Gold Coast/Tweed zone future supply requirements also depends on the impact of this power transfer on the voltage stability of the network supplying the Gold Coast²⁰.

DirectLink northwards operation increases the total amount of customer load that can be supplied in the Gold Coast/Tweed zone. However, DirectLink injects power at a single location at the southern extremity of the Gold Coast/Tweed supply network. It therefore provides limited benefits in addressing future voltage stability limitations that will be caused by insufficient capacity between the source of power for the Gold Coast (primarily power stations in the Brisbane area and west of Brisbane) and customers. As more electricity is transferred into the Gold Coast/Tweed zone across DirectLink, the amount of electricity that can be transferred to the area across the Powerlink and ENERGEX networks, without risking voltage instability, is reduced²¹.

This limits the effectiveness of import across DirectLink to meet forecast load growth in the Gold Coast/Tweed zone. The maximum import of 168MW is equivalent to 42MW of net additional supportable load during peak summer periods in the Gold Coast/Tweed zone²².

3.4.2 Network Support From DirectLink

The above factors were considered in joint planning studies. It has been determined that DirectLink is capable of providing network support to the Gold Coast/Tweed zone to meet supply requirements between late 2005 and late 2006. This recognises the maximum contribution DirectLink is able to make to meeting the annual load growth (25-40MW) in the area. An option comprising a combination of DirectLink network support for the Gold Coast/Tweed zone for the summer of 2005/06 and other action after that time is discussed further in section 5.0.

Southerly transfer across DirectLink may be a potential option to address NSW supply requirements from mid 2006 onwards. DirectLink is not able to supply power to Queensland and NSW simultaneously. However, the Queensland network support requirements are anticipated to occur primarily during the peak summer period, from October 2005 to March 2006, so this should not prevent DirectLink from being utilised to address the northern NSW requirements from mid

¹⁸ Critical outages affecting the capacity of the TransGrid and Country Energy system to supply the Far North Coast region of New South Wales are discussed in the "Emerging Transmission Network Limitations on the New South Wales Far North Coast" document published in August 2003.

¹⁹ An emergency tripping scheme (ETS) is in place in the event of a Lismore-Mullumbimby 132kV or Armidale – Lismore 330kV outage. Other alternative tripping schemes may also be needed if DirectLink is utilised to provide network support to the Gold Coast/Tweed zone.

²⁰ The thermal capability of the network supplying the Gold Coast also needs to be considered as outlined in section 2.3 Refer voltage stability equation published by NEMMCO and implemented in National Electricity Market dispatch systems. This equation describes maximum power transfer limits from South Queensland to the Gold Coast/Tweed zone, and has been revised since the publication of Powerlink's 2003 Annual Planning Report to take account of recent work at Mudgeeraba.

²² In the relevant constraint equation, the DirectLink MW coefficient of –0.7469 means that for every 1MW of DirectLink export to Queensland, the Gold Coast transfer limit reduces by 0.7469 MW. This means the maximum increase in supportable load in the Gold Coast/Tweed zone resulting from 168MW of DirectLink import to Queensland is therefore (1-0.7469)*168, or 42MW. If maximum reactive support (~40MVAr) is provided, this increases the supportable load by 14MW (coefficient of 0.35x40MVAr).

2006 onwards²³. The utilisation of DirectLink in a southerly direction will be assessed as part of a separate economic evaluation to be carried out by TransGrid and Country Energy as necessary to meet their reliability of electricity supply obligations.

If DirectLink is used to meet future Gold Coast/Tweed zone supply requirements, this would require a network support agreement between the owners of DirectLink and Powerlink. Such an agreement would provide for import into Queensland across DirectLink²⁴ when the network flows approach the capability²⁵ of the existing Powerlink and ENERGEX networks supplying the Gold Coast/Tweed zone. Market participants are advised that dispatch of DirectLink to provide network support would occur when the market network service provider is not otherwise transferring the required amount of power in a northerly direction as a result of market price outcomes²⁶.

An arrangement for operating DirectLink under such a commercial network support agreement has been negotiated between Powerlink and the owners of DirectLink. The agreement is not yet finalised, although it is anticipated that it will be signed by the relevant parties in the near future. Details of the proposed contractual arrangements are confidential, but because of the ACCC Regulatory Test requirements for transparency of analysis, the following information is disclosed. Powerlink has determined that imports of up to 160MW²⁷, will be required from DirectLink for this option to ensure a reliable supply to the Gold Coast/Tweed zone can be provided in 2005/06. The total estimated cost of network support for the 2005/06 summer period is \$2.7 Million.

The network support cost comprises fixed and variable components. The actual total cost of the variable component is uncertain. The network support costs will vary depending on bidding patterns in the National Electricity Market (NEM), as the actual cost of network support is dependent on wholesale market price differentials between the NSW and Queensland regions of the NEM (refer additional information section 7.4). The variable network support cost will also vary due to uncertainty with the amount of energy that will be required to meet Gold Coast/Tweed zone customer load. The actual energy unable to be supplied from the Queensland transmission and distribution networks is dependent on half hourly electricity demand, generation pattern, unplanned generator outages, and other factors.

While network support from DirectLink is able to address both voltage stability and forecast thermal limitations in 2005/06, the following year requires a significant increase in the amount of network support. It has been determined that the Queensland requirement for network support in 2006/07 will be beyond the capability of DirectLink under most scenarios due to the factors outlined in section 3.4.1. Hence, augmentation of the Queensland system is required by late 2006. As noted above, DirectLink may then be utilised in a southerly direction to support northern NSW in 2006.

Conclusions on Network Support via DirectLink:

Powerlink and ENERGEX have concluded that network support from New South Wales via the DirectLink market network service is a viable option to address the Gold Coast/Tweed zone supply requirements for the summer of 2005/06. The additional customer load that network support from DirectLink can support is restricted by a variety of factors associated with DirectLink and the networks to which it is connected.

²⁴ assuming all elements of the NSW network supplying DirectLink are in service. TransGrid and Country Energy have agreed to coordinate all planned outages on network elements during the critical summer period between November 2005 and March 2006 to ensure DirectLink's northerly transfer capacity is not unnecessarily compromised.

²³ Peak demand occurs in winter in most areas in northern NSW.

allowing for a critical contingency on one of the 275kV lines from Swanbank to Mudgeeraba/Molendinar

²⁶ It is difficult to predict the direction of DirectLink flow in 2005/06, as this depends on the response by the owners of DirectLink to future generation patterns. Therefore, the network support arrangement may or may not result in counterprice flows across DirectLink between the New South Wales and Queensland regions of the NEM. ²⁷ The MW requirement can be reduced if reactive support is available from DirectLink.

An arrangement for obtaining network support from DirectLink between the owners of DirectLink and Powerlink is close to finalisation. It is anticipated that the terms of this agreement would involve DirectLink network support of up to 160MW during the 2005/06 summer period. The estimated cost of this arrangement would be \$2.7 Million.

Maximum northerly transfer across DirectLink is unable to meet forecast peak demand in the Gold Coast/Tweed zone for the 2006/07 summer. Therefore, a further augmentation would need to be in service by late 2006. Network options able to address this requirement are discussed in the next section.

3.5 Network Options – Queensland Transmission/Distribution

In addition to the consultation process to identify possible alternatives, Powerlink, ENERGEX, TransGrid and Country Energy have carried out joint planning to determine the most appropriate transmission/distribution network option to address the future supply requirements in the Gold Coast/Tweed zone.

3.5.1 Infeasible Options

Multiple options were considered during the joint planning studies. After preliminary analysis, it was concluded that some options are not feasible. These infeasible options are summarised below for the information of interested parties and are not considered further in this Application Notice.

Upgrade existing Swanbank – Mudgeeraba circuits by raising tower structures and retensioning lines where necessary.

This option was rejected because:

- ♦ It would not address either the voltage stability limitation or the overloading of 110kV circuits between Beenleigh and Molendinar that are the critical determinants of network capability in 2005 and 2006.
- ◆ Existing lines would need to be temporarily taken out of service many times to permit the upgrade work. It is estimated that about 54 outages of six hours duration and another ten outages of nine hours duration would be required to complete this work. This would carry a very high risk of customer electricity supply interruptions, without addressing the future supply requirements. This option therefore represents significant non-compliance with the reliability standards.

Additional shunt capacitors (static devices which assist with voltage control)

The addition of further 110kV or 275kV shunt capacitors in the existing Gold Coast/Tweed network was rejected because:

- It would not address either the voltage stability limitation or the overloading of 110kV circuits between Beenleigh and Molendinar that are the critical determinants of network capability in 2005 and 2006.
- Reactive load is already heavily compensated by existing capacitor banks²⁸. Additional capacitor banks could only be switched into service in the existing system after a critical

²⁸ A total of 320MVAr of compensation is located at the transmission substations of Mudgeeraba and Molendinar. Added to this are power factor correction capacitors at local 110/33kV and 110/11kV substations.

	contingency has occurred to avoid excessively high voltages prior to the contingency. Technical limitations associated with automatic reclosing of the transmission circuits would limit the switching times for such additional capacitor banks to about 8 seconds. This would not be fast enough to arrest voltage collapse in all circumstances. ◆ Following loss of a critical 275kV circuit, the voltage step resulting from switching additional capacitor banks could result in voltage fluctuations in excess of that allowed by the voltage quality provisions of the National Electricity Code.
Installation of a Static VAr Compensator at Mudgeeraba (item of substation equipment which can dynamically address voltage stability and control requirements)	Installation of a Static VAr Compensator (SVC) at Mudgeeraba is able to address the immediate voltage control requirements ²⁹ , but was rejected because: ◆ It would not address the overloading of 110kV circuits between Beenleigh and Molendinar for loss of either Swanbank to Mudgeeraba 275kV circuit. ◆ It is therefore only a partial solution and would have to be implemented in conjunction with other action. These other projects can address the network requirements without an SVC, making any combination option more expensive than options without an SVC. An SVC to address the short-term supply requirements was therefore not considered further ³⁰ .

3.5.2 Feasible Augmentation Options

Feasible network options included transmission line augmentation at either 110kV or 275kV. An overview is provided below, with further details provided in section 5.0.

Feasible Queensland Network Augmentations			
110kV Beenleigh to Molendinar	This option involves augmentation of the 110kV network between Beenleigh and Molendinar and installation of a second 110kV 50MVAr capacitor bank at Molendinar by late 2005. Augmentation at 110kV would also require substantial reconstruction of the Molendinar 110kV substation.		
275kV Greenbank to Maudsland	This option involves establishment by late 2005 of a 275kV switchyard at Greenbank, including a 120MVAr 275kV capacitor bank and the construction of an additional double circuit 275kV line from Greenbank to Maudsland. The new circuit would be connected to the recently completed Maudsland to Molendinar 275kV circuit, providing a third 275kV circuit to the Gold Coast/Tweed zone.		

²⁹ Reactive power needs

³⁰ It is anticipated that a Static Var Compensator may be required on the Gold Coast in the longer term – refer 4.1(e).

Feasible Queensland Network Augmentations

"Double tee"
Maudsland to
Molendinar,
followed by
275kV
Greenbank to
Maudsland

The third feasible network augmentation involves the establishment by late 2005 of a second Maudsland 275kV tee using the second circuit of the existing Maudsland to Molendinar double circuit line. This would provide only a small increase in capacity and further augmentation would be necessary by late 2006. This could be achieved by establishment of a 275kV switchyard at Greenbank, including a 120MVAr 275kV capacitor bank and the construction of an additional double circuit line from Greenbank to Maudsland. The new circuit would be connected to the Maudsland to Molendinar 275kV circuit, providing a third 275kV circuit to the Gold Coast/Tweed zone.

It should be noted that the options described above deliver different increments in supply capacity to the Gold Coast/Tweed zone. These differences are taken into account in the economic comparison of options by considering future anticipated/modelled projects that are expected to be required under each option during the planning horizon.

Conclusions on Augmentations of the Queensland Electricity Network

With respect to possible augmentations of the Queensland electricity network, Powerlink and ENERGEX:

- Considered multiple network options, some of which were found to be infeasible;
- Identified three alternative augmentations of the Queensland transmission and distribution network that would address the future supply requirements in the Gold Coast/Tweed zone; and
- These options are considered further in section 5, in combination with network support via DirectLink, anticipated/modelled augmentations to address future supply requirements in Queensland, and anticipated/modelled projects to increase supply capability to the Far North Coast of New South Wales.

4. ANTICIPATED/MODELLED PROJECTS

In accordance with the ACCC Regulatory Test, the economic analysis of options includes future anticipated/modelled projects that may be required within the planning horizon. All options are expected to require a series of augmentations during the fifteen year period analysed to meet the high demand forecast for the Gold Coast/Tweed zone. Works required beyond 2006 are not recommended for approval in this Application Notice, but are included to ensure the proposed augmentations are compared on an equivalent basis. The sensitivity of the analysis to these assumptions is tested through the use of market development scenarios.

Anticipated/modelled projects are considered to address the future supply requirements in the Far North Coast area of New South Wales. Other works are also anticipated to be required to meet ongoing load growth in the Gold Coast/Tweed zone beyond 2006. These anticipated/modelled projects are discussed below:

4.1 Anticipated/Modelled Projects - Gold Coast/Tweed Zone

Anticipated/modelled projects expected to be required to meet supply requirements in the Gold Coast/Tweed zone beyond 2006 have been included in the analysis in accordance with requirements of the ACCC Regulatory Test. These anticipated/modelled projects are common to all of the options considered³¹, with the scope of works and timing varying depending on what works are undertaken in the earlier years.

The variation in timing and scope occurs because some proposed augmentations only address the forecast supply requirements in the short term, and will require further augmentation in the medium term to provide for continuing load growth in the area. Other proposed augmentations provide a large increment in network capability, and therefore provide for forecast load growth further into the future before further action would be required. An overview of each anticipated/modelled project is provided below.

It should be noted some of the anticipated/modelled projects listed below form part of the proposed augmentations in different options (ie – they will be necessary in 2005 or 2006 rather than at a later time).

(a) Molendinar Substation Reconstruction

The Molendinar substation was established in the 1960s. Reconstruction of the 33kV switchyard is expected to be necessary in the future to address switchgear fault ratings and to provide for additional ENERGEX 110kV connections to accommodate additional load growth. Reconstruction of the 110kV busbar³² is expected to be necessary due to thermal capacity limitations.

(b) 275kV Line Capacity to the Gold Coast

The two existing 275kV transmission lines from Swanbank to Mudgeeraba will approach thermal limits in the event of an outage of the other 275kV circuit in the next few years. The timing for anticipated/modelled projects to address this issue is dependent on the amount of power required to be transferred across these lines to satisfy Gold Coast demand growth. On current forecasts, it will be necessary to provide additional 275kV line capacity to the Gold Coast to address this requirement by 2007 to 2009. It will also be necessary to provide a second 275/110kV transformer at Molendinar to allow independent operation of the 275kV line circuits in around 2008.

-

³¹ meaning that by the end of the 15 year period of analysis, the transmission and distribution network configuration would be similar for all options.

³² Item of substation equipment that makes a common connection between several circuits.

(c) Augmentation of the 110kV Network Between Beenleigh and Molendinar

To accommodate the forecast load growth in the area between Beenleigh and the Gold Coast, it is expected to be necessary to upgrade the 110 and 33kV distribution networks in that area. The modelled works include construction of a new 110/33kV substation at Coomera and associated distribution works. They also include rebuilding the existing Beenleigh-Cades County line as a double circuit 110kV line and converting the Cades County-Molendinar 110kV line to double circuit 110kV operation. This section of the network is designed for 110kV operation but one circuit is presently operating at 33kV.

(d) Terranora – Mudgeeraba Double Circuit 110kV Line

Electricity demand in the Tweed zone will eventually grow so that it exceeds the firm capability of the lines which supply Terranora from Mudgeeraba in Queensland. It is anticipated that, depending on the loading on these lines, an additional circuit may be required between these two substations to avoid thermal overloads during contingency conditions beyond 2008.

(e) Ongoing Voltage Support

The forecast load growth in the Gold Coast/Tweed zone may require an ongoing program of voltage support. Compensation of customer load reactive demand will be achieved at the distribution level by ENERGEX and Country Energy. In the longer term, it may also be necessary to install shunt capacitor banks or Static Var Compensators at the 110 or 275kV level to compensate for reactive losses in those systems as the power transfers increase with load growth. However, the requirement for ongoing voltage support is expected to be common to all options in this Application Notice, and has therefore not been included in the analysis³³.

(f) Installation of 275kV Switchgear at Molendinar Substation

By about 2015, there is a forecast need to install a third 275/110kV transformer at Molendinar to provide for the expected long-term load growth in the Gold Coast/Tweed zone. This will require the installation of 275kV switchgear³⁴ to allow independent switching of the incoming lines and transformers at the substation.

4.2 Anticipated/Modelled Projects – Far North Coast NSW

As outlined in section 2.3, TransGrid and Country Energy have identified that action will be required to address approaching supply requirements in the Far North Coast area of NSW.

When evaluating options to address the Gold Coast/Tweed zone requirements, the impacts of each option on these forecast NSW requirements was considered. Joint planning studies by Powerlink, ENERGEX, TransGrid and Country Energy also considered anticipated and modelled projects to address the New South Wales limitations and considered the impact of these on the Queensland network.

TransGrid advised of two alternative network augmentations that could address the forecast requirement in the northern NSW network, namely:

- (a) A 330kV connection between Dumaresq and Lismore.
- (b) A 330kV connection between Armidale and Lismore. Due to the longer distance, this would be a higher cost augmentation than a Dumaresq-Lismore line.

³³ Common works have no impact on the ranking outcome of net present value analysis.

³⁴ Ie - a 275kV busbar

The DirectLink interconnector could provide network support to New South Wales as described in section 3.4. In addition, TransGrid and Country Energy also advised of the possibility that local generation of up to 60MW may complement supply to the far north coast area. It is assumed that such generation would be embedded within the northern NSW distribution network.

For the purposes of the joint planning studies, two potential options to meet northern NSW supply requirements were modelled to assess the impacts on supply to the Gold Coast/Tweed zone:

- A. Network support from either DirectLink or local generation from 2006 onwards.
- B. Dumaresq Lismore 330kV Line in 2006.

Further details are provided below. Together with the feasible Queensland augmentations discussed in section 3.4 and 3.5, consideration of these modelled projects in NSW resulted in eight potential options to address the future supply requirements in the Gold Coast/Tweed zone. These eight options are discussed in more detail in section 5 and in Appendix 2.

4.2.1 Network Support for the Far North Coast of NSW

An arrangement has been included in the analysis in this Application Notice where it is assumed that the northern NSW requirements are addressed through network support from either DirectLink or local embedded generation.

The level of network support required depends on load growth in the Far North Coast area and the location and operating pattern of the network support providers. For the purposes of this Application Notice, it is assumed that sufficient support would be available to address northern NSW requirements for approximately six years from 2006 (in the order of 10MW initially growing to possibly 100MW may be required over this period). From 2012, it is assumed that 330kV network augmentation in New South Wales would be necessary.

The costs included in the financial analysis for this arrangement for network support are based on the offer of network support provided by the owners of DirectLink to Powerlink in relation to meeting the Gold Coast/Tweed zone supply requirements. It is recognised that the future northern New South Wales requirements are of a different quantum and nature, and that an offer of network support by the owners of DirectLink or (as yet uncommitted) local generation may vary considerably from the Queensland offer. However, this is considered to be the best estimate of network support costs available for northern NSW at this point in time.

The primary interrelationships between anticipated/modelled network support arrangements for northern New South Wales and the Queensland supply system are as follows:

- It is expected that any embedded generation output would be consumed locally in northern NSW, and would have minimal impact on the Gold Coast/Tweed zone where load is growing by 25-40MW per year. Limitations on northerly transfer across DirectLink as discussed in section 3.4 would also be likely to restrict the utilisation of any new generation in NSW to assist Queensland network requirements.
- The option being considered of network support via DirectLink to the Gold Coast/Tweed zone followed by 275kV augmentation should not prevent network support being utilised to address the northern NSW requirements from mid 2006 onwards. When DirectLink is flowing northward to support Queensland, it is not able to simultaneously be used to transfer power southward to northern New South Wales. However, the Queensland network support requirements are anticipated to occur primarily during the peak summer period, from October 2005 to March 2006. DirectLink is therefore able to provide network support to Queensland in 2005/06, and still be a viable option for consideration to meet the NSW requirements from 2006 onwards.

The capacity of the Queensland electricity system to support southerly flow on DirectLink for the provision of network support to New South Wales needs to be considered. When DirectLink is flowing in a southerly direction, it places a corresponding additional demand on the transmission network between Queensland power stations and the Gold Coast area. The Queensland network is presently unable to supply this additional demand from DirectLink during peak summer periods, as all capability is required to maintain a reliable power supply to the Gold Coast/Tweed zone. DirectLink is therefore currently restricted from flowing southwards during periods of Gold Coast/Tweed zone peak demand. If DirectLink is to be a viable solution to the New South Wales supply requirements beyond 2006, it is essential that augmentation works are undertaken in Queensland to provide sufficient capacity above the Gold Coast/Tweed zone requirements to transfer power south to NSW³⁵. In the longer term, as the Gold Coast/Tweed zone electricity demand continues to grow, the capacity for additional southward transfer may require additional works. However, no change in timing of longer-term projects is being assumed in this Application Notice.

4.2.2 Dumaresq – Lismore 330kV Transmission Line

An alternative arrangement to address northern NSW requirements involving the completion of a 330kV line from Dumaresq to Lismore was also included in the analysis. A new 330kV supply to Lismore would substantially increase the capability to transfer electricity to the Far North Coast Area of NSW, and would therefore address the identified future supply requirements in the area. Further investigations are required to refine the scope of this modelled project. For the purposes of this Application Notice, it was assumed this modelled project would be achieved by construction of a 330kV line from Dumaresq substation to Tenterfield and rebuilding of the Tenterfield-Lismore 132kV line to 330kV design at an estimated cost of approximately \$100 Million.

There are no significant interrelationships between the anticipated/modelled 330kV augmentation in northern New South Wales and the Queensland supply requirements. Such an augmentation would alleviate some of the restrictions on northward flow on DirectLink during contingencies in the northern New South Wales network, but would have no other impact on the capability to supply customers in the Gold Coast/Tweed zone within the timeframe being considered.

¹

³⁵ Southerly transfer on DirectLink may also require installation of duplicate emergency tripping schemes on the Queensland network elements supplying DirectLink.

5. FEASIBLE OPTIONS

This section provides an overview of the feasible proposed augmentation options identified, with full details of the financial analysis contained in Appendix 2.

The eight options are based on four potential alternatives to address the Gold Coast/Tweed zone requirements, with two variations on each alternative based on different modelled projects to address the requirements in northern New South Wales.

The proposed augmentations to address the Gold Coast/Tweed zone include:

Option 1	110kV Augmentation Beenleigh – Molendinar in late 2005
Option 2	275kV Augmentation Greenbank - Maudsland in late 2005
Option 3	Network support from DirectLink for the summer of 2005/06, followed by 275kV
	Augmentation Greenbank - Maudsland in late 2006
Option 4	"Double tee" connection Maudsland – Molendinar in late 2005, followed by 275kV
-	Augmentation Greenbank - Maudsland in late 2006

For each option, a variation to examine the impact of modelled projects to address northern NSW requirements was considered as follows:

1A to 4A Network support from 2006 onwards, OR;

1B to 4B Construction of Dumaresq – Lismore 330kV Line in 2006.

Other anticipated/modelled projects are also included in each option when they are anticipated to be required to maintain ongoing reliability of supply to the Gold Coast/Tweed zone and the Far North Coast of NSW.

5.1 Proposed Augmentation Option 1A

Proposed Option 1A – 110kV Augmentation Beenleigh to Molendinar (Late 2005)			
Date Regd	Proposed Augmentation	Capital Cost (\$M)	
Late 2005	Augmentation of the 110kV network between Beenleigh and Molendinar.	\$25.5	
Late 2005	Reconstruction of the Molendinar substation.	\$22.0	

Proposed Option 1A involves an initial network augmentation in Queensland at 110kV in late 2005. Under this option, a new 110kV connection would be constructed between Beenleigh and Molendinar. The proposal involves rebuilding the 110kV single circuit line between Beenleigh and Cades County to a double circuit line and converting the Cades County to Molendinar feeder to a double circuit 110kV line (presently one circuit is operating at 33kV and one circuit at 110kV). Option 1A also includes the installation of a 50MVAr capacitor bank at Molendinar substation and related works in the ENERGEX 33kV network.

This would overcome the potential thermal overloads on the existing Beenleigh to Molendinar circuits during a 275kV network contingency by providing extra 110kV network capacity to the Gold Coast/Tweed zone. The additional lines would also provide an additional power path to the area

from power stations in Queensland. This would address the identified voltage stability limit in the existing network by reducing reactive power losses.

Under Option 1A, additional electricity would be transferred to the Gold Coast/Tweed zone via the 110kV network to Molendinar. Under this option, it will therefore be necessary to substantially reconstruct Molendinar substation to cater for the additional power transfer through this substation.

Anticipated/Modelled Projects – Not Recommended in this Application Notice			
Date Reqd	Anticipated Future Projects : Queensland	Capital Cost (\$M)	
Late 2007	Establishment of a 275kV switchyard at Greenbank, including a 120MVAr 275kV capacitor bank. Construction of an additional double circuit line from Greenbank to Maudsland.	\$48.9	
Late 2008	Second Molendinar 275/110kV transformer	\$6.2	
Late 2008	Construction of new Mudgeeraba-Terranora 110kV line	\$8.0	
Late 2015	Installation of 275kV switchgear & third 275/110kV transformer at Molendinar substation	\$15.7	
	Anticipated Future Projects: NSW		
Mid 2006	Network support for northern NSW for six years to 2012	\$18.0 ³⁶	
Late 2012	Construction of a new Dumaresq-Tenterfield 330kV line, rebuilding of the existing Tenterfield-Lismore 132kV line for 330kV operation and associated substation works at Dumaresq and Lismore.	\$100	

The proposed 110kV augmentation in Option 1A provides a modest increment in supply capacity to the Gold Coast/Tweed zone. It is a short-term solution, as it can only address the identified future supply requirements in the area for two years before further augmentation will be necessary. At this time, it is assumed that a 275kV augmentation between Greenbank and Maudsland will be required to address forecast thermal overloads in the existing 275kV network.

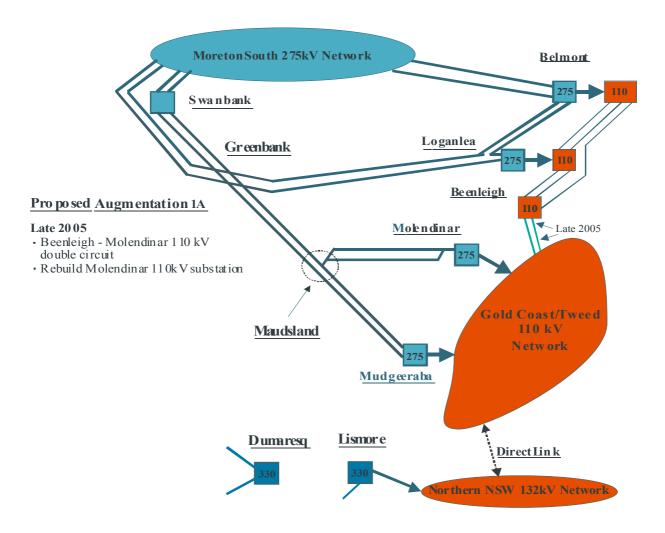

Other anticipated/modelled projects are also expected to be required in Queensland, as described in section 4.1. The timings for these augmentations under Option 1A are shown in the table above, and have been determined through planning studies which examined how long the proposed and anticipated works will address the future supply requirements before further action is required.

Option 1A assumes that northern NSW supply requirements are addressed through a modelled arrangement for network support from either DirectLink or embedded generation from mid 2006 onwards. It is assumed that this is capable of addressing the Far North Coast of NSW supply requirements for six years, with network augmentation being required in NSW by 2012.

_

³⁶ Refer section 4.2.1

Figure 3 – Proposed Option 1A 110kV Network Augmentation in late 2005

5.2 Proposed Augmentation Option 1B

Proposed augmentation 1B is the same as Option 1A except that it is assumed the modelled project to address the future supply requirements in northern New South Wales involves the construction of a 330kV transmission line from Dumaresq to Lismore by mid 2006 as described in section 4.1.2.

5.3 Proposed Augmentation Option 2A

Proposed Option 2A – Greenbank– Maudsland 275kV Transmission Line (Late 2005)			
Date Reqd Late 2005	Proposed Augmentation Establishment of a 275kV switchyard at Greenbank, including a 120MVAr 275kV capacitor bank and the construction of an additional double circuit line from Greenbank to Maudsland.	Capital Cost (\$M) \$48.9	

Proposed Option 2A involves transmission network augmentation in Queensland at 275kV.

The works in proposed Option 2A, shown in Figure 4, involve establishment of a new 275kV switchyard at Greenbank in the Logan area. This would improve voltage stability in the network supplying the Gold Coast/Tweed zone by providing a switching point closer to the Gold Coast/Tweed zone. The proposed works would also include the installation of a 120MVAr capacitor bank at the new Greenbank switchyard to provide additional voltage support.

Option 2A also includes construction of a 43km section of new transmission line between Greenbank and Maudsland, 12km inland from Molendinar, by late 2005. The new circuit would be connected to the existing Maudsland to Molendinar 275kV circuit. It would initially operate as a single circuit, providing additional 275kV line capacity to the Gold Coast/Tweed zone. This proposed new line addresses both the potential voltage collapse (by reducing the loading on remaining lines during a 275kV contingency and therefore reducing reactive power losses) and the potential 110kV line overloads (by redistribution of network power flows away from the 110kV lines to the 275kV lines).

Anticipated/Modelled Projects – Not Recommended in this Application Notice			
Date Regd	Anticipated Future Projects: Queensland	Capital Cost (\$M)	
Late 2007	Molendinar 110kV Substation Reconstruction	\$22.0	
Lata 2009	Second Molendinar 275/110kV transformer	\$6.2	
Late 2008	Construction of new Mudgeeraba-Terranora 110kV line	\$8.0	
Late 2009	Augmentation of 110kV Network Beenleigh - Molendinar	\$25.5	
Late 2009	Installation of 275kV switchgear & third 275/110kV transformer at Molendinar substation	\$15.7	
	Anticipated Future Projects: NSW		
Mid 2006	Network support for northern NSW for six years to 2012	\$18.0 ³⁷	
Mid 2006 Mid 2012	Construction of a new Dumaresq-Tenterfield 330kV line, rebuilding of existing Tenterfield-Lismore 132kV line for 330kV operation and substation works at Dumaresq and Lismore.	\$100	

³⁷ Refer section 4.2.1

Option 2A assumes anticipated/modelled projects will be required in Queensland, as described in section 4.1. The timings for these augmentations under Option 2A are shown in the table above, and have been determined through planning studies which examined how long the proposed and anticipated works will address the future supply requirements before further action is required.

Option 2A also assumes that northern NSW supply requirements are addressed through a modelled arrangement for network support from mid 2006 onwards. It is assumed that this is capable of addressing the Far North Coast of NSW supply requirements for six years, with network augmentation being required in NSW by 2012.

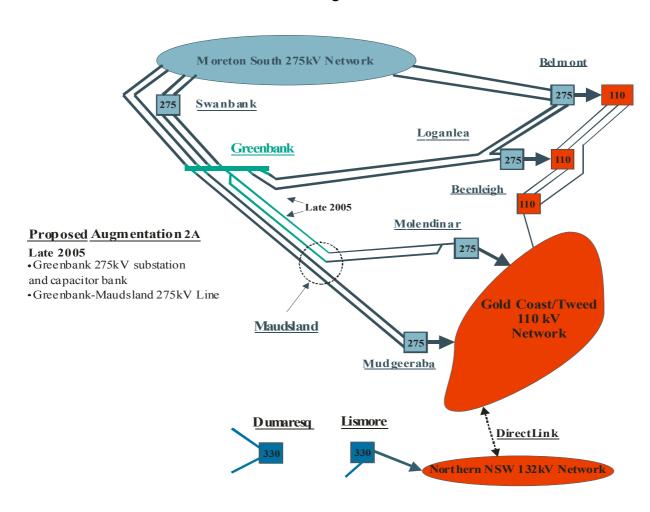

Figure 4 – Proposed Option 2A 275kV Network Augmentation in late 2005

5.4 Proposed Augmentation Option 2B

Proposed Option 2B is the same as Option 2A, except the modelled project to address the future supply requirements in northern New South Wales involves the construction of a 330kV transmission line from Dumaresq to Lismore instead of network support from DirectLink or embedded generation.

5.5 Proposed Augmentation Option 3A

Proposed Option 3A – DirectLink network support for 2005/06 summer followed by 275kV Greenbank – Maudsland Transmission Line by late 2006			
Date Reqd	Proposed Augmentation	Capital Cost (\$M)	
Late 2005	DirectLink network support of up to160MW for 2005/06 summer	\$2.7 ³⁸	
Late 2006	Establishment of a 275kV switchyard at Greenbank, including a 120MVAr 275kV capacitor bank and the construction of an additional double circuit line from Greenbank to Maudsland.	\$48.9	

Proposed Option 3A involves DirectLink network support for the Gold Coast/Tweed zone for the 2005/06 summer period. The network support via DirectLink reduces the amount of power that has to be transferred across the Powerlink and ENERGEX networks to the Gold Coast during critical contingencies. It therefore overcomes the forecast voltage issues and thermal overloads in the existing transmission and distribution network and defers the need for other action.

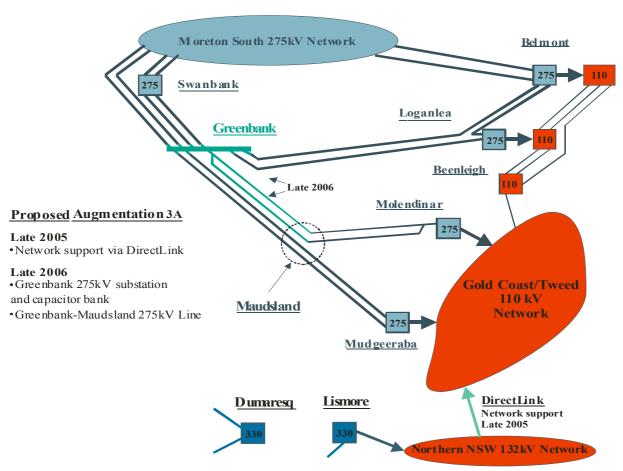

As discussed in section 3.4, there are restrictions on the ability of DirectLink to provide network support to the Gold Coast/Tweed zone for a longer period than one year. Other action is therefore required to meet supply requirements from late 2006 onwards. Option 3A proposes the establishment of a new 275kV switchyard at Greenbank in the Logan area, and construction of a 43km section of new transmission line between Greenbank and Maudsland, by late 2006. This involves the same works as described in option 2A, but deferred by one year due to the proposed network support arrangement with DirectLink.

Anticipated/Modelled Projects – Not Recommended in this Application Notice			
Date Regd	Anticipated Future Projects : Queensland	Capital Cost (\$M)	
Late 2007	Molendinar 110kV Substation Reconstruction	\$22.0	
Late 2008	Second Molendinar 275/110kV transformer	\$6.2	
Late 2008	Construction of new Mudgeeraba-Terranora 110kV line	\$8.0	
Late 2009	Augmentation of 110kV Network Beenleigh - Molendinar	\$25.5	
Late 2015	Installation of 275kV switchgear & third 275/110kV transformer at Molendinar substation	\$15.7	
	Anticipated Future Projects : NSW		
Mid 2006	Network support for northern NSW for six years to 2012	\$18.0 ³⁹	
Late 2012	Construction of a new Dumaresq-Tenterfield 330kV line, rebuild of the existing Tenterfield-Lismore 132kV line for 330kV operation and associated substation works at Dumaresq and Lismore.	\$100	

³⁸ Refer section 7.4

It should be noted that no deferral of anticipated/modelled projects beyond 2006 is achieved through the proposed provision of network support by DirectLink in 2005/06 in Option 3A⁴⁰. The anticipated/modelled projects for Option 3A are therefore the same as Option 2A.

Figure 5: Proposed Option 3A
DirectLink Network Support 2005/06
275kV Network Augmentation Late 2006

5.6 Proposed Augmentation Option 3B

Proposed Option 3B is the same as Option 3A, except the modelled project to address the future supply requirements in northern New South Wales involves the construction of a 330kV transmission line from Dumaresq to Lismore instead of network support from DirectLink or embedded generation.

³⁹ Refer section 4.2.1

⁴⁰ When DirectLink is not providing network support, the total supply capacity to the Gold Coast/Tweed zone is determined by the capacity of the existing transmission and distribution network.

5.7 Proposed Augmentation Option 4A

Proposed Option 4A – Double tee Maudsland – Molendinar by late 2005 followed by 275kV Greenbank – Maudsland Transmission Line by late 2006			
Date Reqd	Proposed Augmentation	Capital Cost (\$M)	
Late 2005	Second Maudsland – Molendinar 275kV tee connection	\$3.6 ⁴¹	
Late 2006	Establish a 275kV switchyard at Greenbank, including a 120MVAr 275kV capacitor bank. Construct an additional double circuit line Greenbank -Maudsland.	\$48.9	

The existing Maudsland-Molendinar 275kV tee connection has been constructed as a double circuit line, but operates as a single circuit connected to only one transformer at Molendinar substation. Proposed Option 4A involves the establishment by late 2005 of a second Maudsland 275kV tee using the second circuit of the existing Maudsland to Molendinar double circuit line.

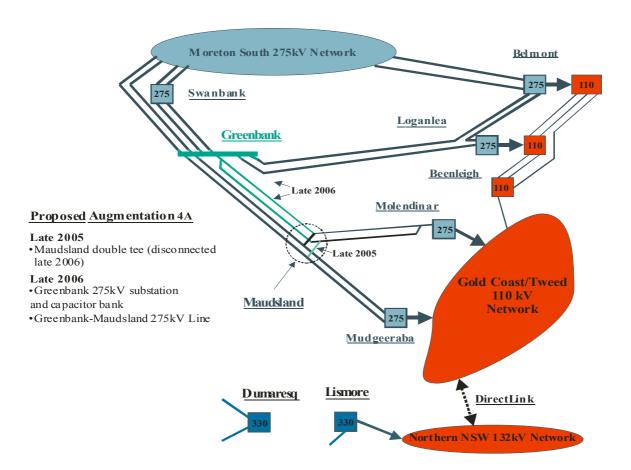

At present, an outage of the existing Maudsland – Molendinar tee connection is the worst credible single contingency as no electricity can be injected into Molendinar at 275kV during an outage of this circuit. Establishment of a second tee connection would reduce the impact of an outage of the existing tee connection, providing a marginal increase in transfer capacity to the Gold Coast/Tweed zone.

Further augmentation would be necessary the following year to meet the Gold Coast/Tweed zone supply requirements. Option 4A proposes the establishment of Greenbank switchyard and the construction of a 43km section of new 275kV transmission line between Greenbank and Maudsland, by late 2006. This involves the same works as described in option 2A, but deferred by one year due to establishment of the double tee.

Anticipated/Modelled Projects – Not Recommended in this Application Notice			
Date Reqd	Anticipated Future Projects : Queensland	Capital Cost (\$M)

⁴¹ Comprises \$1.46M operating expenditure and \$2.17M capital expenditure

Figure 6 – Proposed Option 4A "Double Tee" Late 2005 275kV Network Augmentation Late 2006

5.8 Proposed Augmentation Option 4B

Proposed Option 4B is the same as Option 4A, except the modelled project to address the future supply requirements in northern New South Wales involves the construction of a 330kV transmission line from Dumaresq to Lismore instead of network support from DirectLink or embedded generation.

⁴² Refer section 4.2.1

6. MARKET DEVELOPMENT SCENARIOS

6.1 Context for Evaluation of Options

All feasible solutions to the identified supply requirements must be viewed in the context of wider developments in the National Electricity Market:

- The Queensland Government is proceeding with the implementation of its policy requirement for Queensland energy retailers to source 13% of their energy from gas-fired generation from 1 January 2005. The 13% Gas Scheme is designed to deliver on the government policy objectives of diversifying the State's energy mix towards a greater use of gas and encouraging new gas infrastructure in Queensland, while reducing the growth in greenhouse gas emissions;
- Commonwealth legislation has been in effect since 1 January 2001 to encourage increased generation from renewable energy sources. Powerlink has incorporated independent forecasts of additional renewable energy generation into the forecasts of demand and energy used in assessing future supply requirements;
- NEMMCO's Statement of Opportunities (SOO) issued in July 2003 contained information on existing and committed generation developments in Queensland. There is currently a considerable margin between supply capacity and demand, with several large new generating units commissioned in Queensland in the past two years.
- The large margin between supply capacity and demand for Queensland as a whole does not apply to the Gold Coast/Tweed zone. As outlined in section 2.2, electricity demand in the Gold Coast zone (which must be transmitted from power stations outside the zone) is growing at an average of 3.6% per year over the next 10 years and at about 6% per year over the next three years. This is equivalent to between 25 and 40MW per year. Apart from small amounts of generation embedded in the distribution systems (which is already accounted for in the ENERGEX and Country Energy load forecasts) there has been no net increase in power generation installed in the Gold Coast/Tweed zone to match this demand growth.
- Historical market data shows that generation dispatch during the past twelve months has
 resulted in southward flows on the Queensland-New South Wales interconnector (QNI) and on
 the DirectLink market network service provider (ie from Queensland to New South Wales) for
 the majority of the time. This trend is anticipated to continue in the short term. However, as
 DirectLink operation and flows across QNI depend on market bidding behaviour, new
 generation investment etc, the direction that power will flow across these interconnectors in the
 future cannot be presumed.

6.2 Assumed Market Development Scenarios

The ACCC Regulatory Test requires that options to address network requirements be assessed against a number of plausible market development scenarios. These scenarios need to take account of:

- the existing system;
- future network developments;
- variations in load growth;
- committed generation and demand side developments;
- potential generation and demand side developments.

The purpose of utilising this approach is to test the Net Present Value costs of the solutions being evaluated under a range of plausible scenarios.

6.2.1 Existing Network and Future Transmission Developments:

No market development scenarios have been developed related to new network developments proposed by Powerlink, ENERGEX, Country Energy or TransGrid outside the Gold Coast/Tweed area. These are independent of the future supply requirements that are the subject of this report, and are considered to be common to all options analysed. Future network developments, in both NSW and Queensland, which are relevant to the Gold Coast/Tweed area have been included as anticipated/modelled projects in the analysis.

6.2.2 Variations in Load Growth

Four market development scenarios have been developed to consider sensitivity to variations in customer electricity demand:

Scenario	Forecast Electricity Demand Level
Scenario A	Medium (medium economic growth and typical weather conditions)
Scenario B	High (higher economic growth and typical weather conditions)
Scenario C	Low (lower economic growth and typical weather conditions)
Scenario D	Embedded Generation (medium economic growth and typical weather conditions with 2005/06 demand reduced by 30MW)

These scenarios are based on typical weather (50% probability of exceedance) forecast for electricity usage, with varying levels of economic growth⁴³. The forecasts include all known information about existing and planned demand side initiatives, and also include independent forecasts of local embedded generation developments. The forecasts do not consider extreme temperature conditions.

The Gold Coast area has to date been one of the highest load growth areas in Australia. Demand is forecast to increase at more than 3% per year over the next ten years, with higher than average growth over the next 2-3 years. Scenarios A, B and C have been developed based on different levels of demand growth (from 2.2%p.a to 3.9%p.a over a ten year period). Scenario D has been developed to assess the sensitivity of the analysis to an outcome where electricity demand on the transmission system is lower than anticipated over the next few years, but then continues at a medium growth rate thereafter. This could occur through the installation of additional small generation embedded within the distribution network and/or a reduction in the recent high levels of development in the Gold Coast/Tweed zone. As noted in section 3.3.2, there are no indications that embedded generation could occur by the required timeframe, but Scenario D has been developed to assess sensitivity of the analysis results to this scenario.

6.2.3 Existing and Committed Generators:

As noted in section 3.2, there are no major power stations in the Gold Coast/Tweed area and no recently committed generators proposing to establish in the Gold Coast/Tweed zone prior to 2005. For this reason, no scenarios have been developed in which the output of existing and/or committed generators is increased.

⁴³ Refer 2003 Annual Planning Report and 'Request for Information' document published in August 2003.

However, due to the inclusion of DirectLink network support as an option, it is necessary to assess how the operation of existing generators in the National Electricity Market as a whole may influence the dispatch of the DirectLink market network service provider. Powerlink Queensland has sought advice from ROAM Consulting on the impacts of market dispatch and wholesale market pricing on the cost of network support from DirectLink. ROAM Consulting carried out market simulations to examine potential generation patterns and resulting regional price differentials. For the purposes of this Application Notice, the cost of network support in all scenarios has been based on the average price differential between the NSW and Queensland market regions based on the market simulations by ROAM Consulting. Sensitivity analysis has been carried out to test the sensitivity of the analysis results to changes in this assumption (refer sections 7.4 and 8.2).

6.2.4 Potential New Generation:

NEMMCO's 2003 Statement of Opportunities indicated that additional investment in major generation may be required in the medium term, but any such investment is considered unlikely to occur in the Gold Coast/Tweed zone. No new stand-alone generation was proposed in response to the Request for Information document, and is considered unlikely because of a lack of economic fuel sources and the high density of residential and commercial development within the area. Hence no market development scenarios have been developed to consider the establishment of major new stand-alone generators in the Gold Coast/Tweed zone.

Smaller generation or demand side developments may occur in the Gold Coast/Tweed area. The impact of potential embedded generation developments has been considered through the development of Scenario D, where demand on the electricity network supplying the Gold Coast/Tweed zone is forecast to be reduced by 30MW in 2005/06⁴⁴.

.

⁴⁴ This scenario assumes 30MW demand reduction at the high load centres of Southport, Surfers Paradise and Broadbeach. The actual impact of embedded generation would depend on its location, distance from load centres etc.

7. FORMAT AND INPUTS TO ANALYSIS

7.1 Regulatory Test Requirements

The requirements for the comparison of options to address an identified network limitation are contained in the Regulatory Test prescribed by the Australian Competition and Consumer Commission (ACCC)⁴⁵.

The Regulatory Test requires that the recommended option be the option that "maximises the net present value of the market benefit having regard to a number of alternative projects, timings and market development scenarios". To satisfy the Test, a proposed augmentation must achieve a greater market benefit in most, *but not necessarily all*, credible scenarios.

The Regulatory Test contains guidelines for the methodology to be used to calculate the net present value (NPV) of the market benefit. For example, where an augmentation is required to satisfy minimum network performance requirements (ie – a reliability augmentation), the methodology published by the ACCC defines "market benefit" as the total net cost to all those who produce, distribute and consume electricity in the National Electricity Market. That is, the option with the lowest net present value cost maximises the market benefit.

Information to be considered includes the 'efficient operating costs of competitively supplying energy to meet forecast demand' and the cost of complying with existing and anticipated laws. However, the Regulatory Test specifically excludes indirect costs, and costs that cannot be measured as a cost in terms of financial transactions in the electricity market.

7.2 Inputs to Analysis

A solution to address future supply needs in the Gold Coast/Tweed zone as outlined in this document is required to satisfy reliability requirements linked to Schedule 5.1 of the National Electricity Code, the requirements of the Queensland Electricity Act, Powerlink's Transmission Authority and ENERGEX's Distribution Authority⁴⁶.

According to the ACCC Regulatory Test, this means that the costs of all options must be compared, and the least cost solution is considered to satisfy the Regulatory Test. The results of this evaluation, carried out using a cash flow model to determine the Net Present Value (NPV) of the various options, are shown in section 8.0.

Cost inputs to the NPV analysis are described below.

7.3 Cost of Network Augmentations:

The cost of the Queensland and New South Wales network augmentations and anticipated/modelled projects outlined in the options in section 5.0 have been estimated by Powerlink, ENERGEX, Country Energy and TransGrid⁴⁷. Sensitivity studies have been carried out using variations in the capital cost estimates of plus or minus 15% (see section 8.3).

The financial analysis considers all cost impacts of the proposed network augmentations to market participants as defined by regulatory processes. The estimated saving in the cost of network

⁴⁵ Powerlink is required to evaluate options for new transmission developments under the Regulatory Test in accordance with clause 5.6 of the National Electricity Code.

⁴⁶ Refer section 3.0.

⁴⁷ Each network service provider estimated the costs of proposed augmentations in their own networks.

losses for each option has been included based on the assumption of typical load factor and an average cost of losses of \$25/MWh⁴⁸. Sensitivity studies have also been carried out on the assumed cost of losses (see section 8.3).

7.4 Cost of Network Support:

As noted earlier in this document, the cost of network support for the Gold Coast/Tweed zone from DirectLink has been negotiated between the owners of DirectLink and Powerlink. The estimated total cost of \$2.7M has been incorporated into the financial analysis of options. Sensitivity analysis has been carried out to assess the sensitivity of the analysis to a higher or lower cost of network support.

The commercial arrangements for the provision of network support by DirectLink are confidential. However, the following background information on the process to estimate the cost of network support required for the Gold Coast/Tweed zone is provided for the information of market participants and other interested parties:

- The capability of the existing transmission and distribution network to transfer electricity to the Gold Coast/Tweed zone was determined using the voltage stability constraint equation as implemented in NEMMCO's market dispatch systems.
- The amount of network support required from DirectLink in 2005/06 was estimated based on the network capability and the load duration curves from the past four summer periods.
- This analysis estimated the amount of peak summer demand that would be unable to be supplied from the existing network without network support from DirectLink, and the estimated periods of time that network support would be required. It was estimated that up to 160MW⁴⁹ would be required from DirectLink in 2005/06 to maintain a reliable electricity supply to the Gold Coast/Tweed zone. The total number of market trading intervals in which DirectLink could be required to flow in a northerly direction to support the Gold Coast/Tweed zone was estimated at 200 (ie up to 100 hours over the 2005/06 summer). Due to the uncertainty associated with future predictions of variables including electricity demand and generation pattern, the estimated requirement for network support will vary depending on actual customer demand, actual generation dispatch etc.
- The cost of network support from DirectLink is related to both the MW/MVAr requirement and the wholesale market price differential between the regions of NSW and Queensland. DirectLink is a market network service provider, meaning that its normal operation depends on market bidding patterns and market price differentials between Queensland and New South Wales. The negotiated agreement for network support provides for DirectLink to flow in a northerly direction whenever necessary to meet customer electricity demand in the Gold Coast/Tweed zone. This may result in counter-price flows, for which the owners of DirectLink would be compensated under the network support agreement.
- Powerlink asked ROAM Consulting Pty Ltd⁵⁰ to prepare a market forecast to evaluate the impacts on network support costs of pool price differentials between the Queensland and NSW regions of the NEM. Estimated costs of network support in this Application Notice are based on the average regional price differential identified during the market simulations conducted by

_

⁴⁸ Network losses are a function of the length and capacity of individual network elements, and the power being transferred through them. In heavily loaded systems, additional network elements reduce the amount of power that must be forced through the existing network, and therefore reduce total losses.

⁴⁹ The MW requirement can be reduced if reactive support is available from DirectLink.

⁵⁰ ROAM Consulting Pty Ltd has considerable experience in electricity market simulations.

ROAM Consulting. Sensitivity analysis was carried out on the full set of results from the ROAM study to consider the impact of a change in the assumed regional price differential.

- The estimated cost of grid support also includes the installation of appropriate emergency control systems by the owners of DirectLink to allow northerly transfers to the required level.

It must be emphasised that the total network support costs are an estimate only, based on the forecast energy that may be unable to be supplied by the Powerlink and ENERGEX networks and estimated regional price differentials. Actual costs of network support will vary. Should a network support option be adopted, DirectLink has indicated its willingness for the full commercial details to be disclosed on a confidential basis to the ACCC for regulatory review purposes.

Interested parties should also note that the owners of DirectLink have advised that they are currently investigating the conversion of DirectLink from a market network service provider to a regulated interconnector. Should DirectLink be operating as a regulated service prior to the summer of 2005/06, the option of obtaining network support from DirectLink for the Gold Coast/Tweed zone would still be feasible. The network support arrangement agreed between Powerlink and the owners of DirectLink provides for network support to be provided to the Gold Coast/Tweed zone in 2005/06 at no charge should the interconnector become regulated prior to that time. In such circumstances, the owners of DirectLink would obtain regulated revenue and no network support payments would be required.

7.5 Other Inputs to Analysis:

While a solution must be adopted by late 2005 to overcome the future supply requirements, the NPV analysis contains anticipated projects required to address longer-term supply reliability requirements, excepting some future developments common to all options which have been excluded. The sensitivity of the timing of these anticipated projects to load growth and generation development scenarios (and therefore the incidence of the capital expenditure) has been taken into account in the financial analysis.

Capital and operating costs for some items which are common to all options were not included in the analysis. These common costs include the capital and operating costs of other future transmission works, where these costs are independent of the identified future supply requirements or where they are independent of the proposed augmentation. As such, they have no impact on the relative ranking of options resulting from the analysis. Where the timing of common works is affected by the proposed options, the cost of the other works proposed has been included in the NPV analysis.

8. FINANCIAL ANALYSIS

The economic analysis undertaken considered the net present value (NPV) of net market benefits of alternative options over the fifteen year period from 2003/04 to 2017/18. Full details of this analysis are contained in Appendix 2.

8.1 Net Present Value Analysis

Financial analysis was carried out to calculate and compare the Net Present Value (NPV) of the costs to market participants of each option under the range of assumed market development scenarios.

A fifteen year analysis period was selected, as an appropriate period for financial analysis. A discount rate of 10% was selected as a relevant commercial discount rate, and sensitivity analysis was conducted to test this assumption.

Under the Regulatory Test, it is the ranking of the options which is important, rather than the actual net present value results. This is because the Regulatory Test requires the recommended option to have the <u>lowest net present value cost</u> compared with alternative projects.

The following table is a summary of the economic analysis contained in Appendix 2. It shows the net present value of each alternative, and identifies the best ranked option, for the range of scenarios considered.

Discount rate 10%		ario A ad growth		ario B d growth		ario C d growth	30MW of	ario D embedded ration
Option 1A 110kV Augmentation in Qld (Modelled Projects include Network Support to NSW)	NPV (\$M)	\$91.15	NPV (\$M)	\$98.96	NPV (\$M)	\$78.29	NPV (\$M)	\$81.57
	Rank	4	Rank	4	Rank	4	Rank	4
Option 1B 110kV Augmentation in Qld (Modelled Projects include Dumaresq - Lismore 330kV line in NSW)	NPV (\$M)	\$112.05	NPV (\$M)	\$117.37	NPV (\$M)	\$99.67	NPV (\$M)	\$100.62

Option 3A DirectLink Network Support North followed by 275kV Augmentation in Qld (Modelled Projects include Network Support to NSW)	NPV (\$M)	\$86.68	NPV (\$M)	\$94.32	NPV (\$M)	\$71.84	NPV (\$M)	\$76.49
	Rank	1	Rank	1	Rank	2	Rank	2
Option 3B DirectLink Network Support North followed by 275kV augmentation in Qld (modelled projects include Dumaresq - Lismore 330kV line in NSW)	NPV (\$M)	\$107.58	NPV (\$M)	\$112.73	NPV (\$M)	\$93.21	NPV (\$M)	\$95.54
	Rank	5	Rank	5	Rank	6	Rank	6
Option 4A Maudsland Double Tee followed by 275kV augmentation in Qld (Modelled Projects include Network Support to NSW)	NPV (\$M)	\$86.93	NPV (\$M)	\$94.58	NPV (\$M)	\$70.10	NPV (\$M)	\$74.73
	Rank	2	Rank	2	Rank	1	Rank	1
Option 4B Maudsland Double Tee followed by 275kV Augmentation in Qld (Modelled Projects include Dumaresq - Lismore 330kV line in NSW)	NPV (\$M)	\$107.84	NPV (\$M)	\$112.99	NPV (\$M)	\$91.47	NPV (\$M)	\$93.78
	Rank	6	Rank	6	Rank	5	Rank	5

As can be seen in the table above, Directlink network support in 2005 and 275kV augmentation in 2006 (option 3A) is the lowest cost option in Scenarios A and B.

In Scenarios C & D, both DirectLink network support and the Maudsland double tee are able to address the Gold Coast/Tweed zone supply requirements for two years due to the lower levels of electricity demand assumed in these scenarios. The DirectLink network support option (option 3A) is a higher cost option than the Maudsland double tee (option 4A) in these scenarios primarily because the fixed component of the network support charge would be paid for two years.

An option must be the lowest cost option in the majority of scenarios for it to satisfy the ACCC Regulatory Test. As shown in the table above, Option 3A and Option 4A are the lowest cost options in an equal number of scenarios. However, Scenario A (medium growth scenario) is the scenario considered most likely to occur. Powerlink and ENERGEX therefore consider that Option 3A satisfies the Regulatory Test. In addition, DirectLink is an existing facility and therefore avoids implementation issues associated with Option 4A such as the need to temporarily take existing lines out of service to allow the double tee arrangement to be connected.

8.2 Sensitivity Analysis

In addition to examining the impact of market development scenarios, the sensitivity of the option ranking to other critical parameters was also examined.

The effect of varying these parameters over their credible range was investigated using standard Monte Carlo techniques⁵¹. The following table shows the parameters that were investigated in the sensitivity analysis, the distribution that was assumed for each parameter and the range of values.

Parameter	Distribution
Capital Cost of Transmission Augmentations	The capital cost of the proposed augmentations and anticipated/modelled projects was tested for sensitivity to variations of plus or minus 15% from the expected value. The variation in each cost was modelled as a triangular distribution with the assumption that the costs are statistically independent. This means that the cost of each network component is allowed to vary within plus and minus 15% independently of the over or underspend of the other components.
Cost of losses	The sensitivity to the average cost of losses was tested by allowing this parameter to vary randomly between \$20/MWh and \$30/MWh using a triangular distribution with a mode of \$25/MWh.
Cost of Network Support	The cost of network support was tested for sensitivity to wholesale market regional price differentials. ROAM Consulting provided a forecast of these differentials (see section 7.4). The average was used for the base economic analysis. The sensitivity analysis used the complete distribution of results from the ROAM study.

The Monte Carlo analysis assigns a value to each of the above parameters according to its distribution and then ranks the options. This simulation is done many times (in this case, 1,000 times) to cover a large number of combinations of parameters. The analysis identifies which option is the best ranked option (the option that has the lowest cost on an NPV basis for the largest number of samples) and gives the frequency for which this option 'wins'.

In addition to the above sensitivities, the sensitivity of the ranking of options to the discount rate assumption was also investigated by repeating the above analysis with a discount rate of 8%, 10% and 12%. The following table shows the 'winning option' and the frequency for which it 'wins' for each scenario and discount rate across the range of parameters assessed.

⁵¹ Using the @Risk add-in for Microsoft Excel.

		Discount Rate	
	8%	10%	12%
Scenario A - Medium Load Growth	3A(100%)	3A(99%)	3A(88%)
Scenario B - High Load Growth	3A(100%)	3A(99%)	3A(88%)
Scenario C - Low Load Growth	4A(100%)	4A(100%)	4A(100%)
Scenario D – 30 MW of embedded generation	4A(100%)	4A(100%)	4A(100%)

As can be seen in this table, the results of the sensitivity analysis are consistent with the base case economic analysis, and the outcome is robust in terms of the variations in parameters assessed.

On the basis of the financial analysis and the sensitivity studies, Option 3A is the option that satisfies the ACCC Regulatory Test. Technical details and the construction timetable for Option 3A are provided in Appendix 1.

8.3 Inter-Network Impact

Powerlink is required under the National Electricity Code to assess whether a proposed new large network asset is reasonably likely to have a material inter-network impact. Powerlink and TransGrid have determined that the proposed new large network asset (Option 3A) will not impose power transfer constraints or adversely impact on the quality of supply within the New South Wales network.

9. CONCLUSIONS

The following conclusions have been drawn from the analysis presented in this report:

- ♦ Powerlink and ENERGEX must take action now to ensure a continued reliable electricity supply to the Gold Coast/Tweed zone in 2005 and 2006, and to position the area for future growth.
- Such action is necessary to comply with electricity reliability standards which Powerlink and ENERGEX must meet, as the local Transmission Network Service Provider and Distribution Network Service Provider respectively. Interruptions to power supply during single network contingencies are not consistent with these reliability standards. Augmentations proposed in this document will prevent such interruptions during a critical contingency in the 275kV network supplying the Gold Coast/Tweed zone. They are therefore 'reliability augmentations' as defined in the National Electricity Code.
- Future supply requirements are also expected to arise in northern New South Wales by mid 2006 during the most critical single contingency. Anticipated/modelled projects to address this future need were considered in the analysis of options to address the Gold Coast/Tweed zone requirements.
- Powerlink and ENERGEX carried out a consultation process in August 2003 in order to identify any non-network solutions to address the Gold Coast supply requirements. Joint planning studies were carried out between Powerlink and ENERGEX and their counterparts in New South Wales, TransGrid and Country Energy to evaluate potential options to address the future supply requirements in the Gold Coast/Tweed zone. Following the consultation and joint planning process, Powerlink and ENERGEX concluded that network support for the summer of 2005/06 via DirectLink is the only viable alternative to network augmentation. Three network augmentations and a combined option involving DirectLink network support for 2005/06 were evaluated in detail.
- ◆ Economic analysis carried out in accordance with the Regulatory Test has identified that proposed augmentation Option 3A "Network Support from DirectLink for the 2005/06 summer, followed by 275kV Augmentation Greenbank-Maudsland in 2006 is the least-cost solution over the fifteen year period of analysis in two of the four scenarios considered, assuming a modelled project for DirectLink to provide network support to NSW from 2006. Sensitivity analysis showed that the analysis is robust to variation in capital cost and other assumptions. The scenarios in which option 3A is not the least cost option are considered to have a lower probability of occurring, as they are low growth and reduced demand scenarios. As Option 3A is the lowest cost option in the most likely scenario, Option 3A is considered to satisfy the ACCC Regulatory Test. This conclusion is subject to the finalisation of a satisfactory network support agreement between Powerlink and the owners of DirectLink, which is anticipated in the near future.
- ◆ In addition to maximisation of benefit, the ACCC Regulatory Test requires that a transmission network service provider optimise the timing of any proposed network augmentation that is justified under the Regulatory Test. It is evident from the analysis that action is required prior to late 2005, in order to maintain a reliable power supply to customers in the Gold Coast/Tweed zone. Any deferral of timing beyond this date will result in unacceptable network reliability.
- No construction work is necessary for the provision of network support from DirectLink. The commercial agreement will be implemented should the draft recommendation in this Application Notice be adopted. Construction of the subsequent network augmentation as per Option 3A will commence in late 2004 to ensure completion by late 2006.

10. DRAFT RECOMMENDATION

Based on the conclusions drawn from the analysis and the Code requirements relating to "New Large Network Assets", it is recommended that the following action be implemented to address the future supply requirements in the Gold Coast and Tweed Area:

- Powerlink and the owners of DirectLink to enter into a commercial agreement for the provision of network support via import into Queensland from New South Wales over the DirectLink interconnector for the 2005/06 summer period. This arrangement has an estimated total cost of \$2.7M. This recommendation is subject to the finalisation of a satisfactory commercial agreement, which is anticipated in the near future.
- Powerlink to establish a 275kV switchyard at Greenbank and construct a double circuit 275kV transmission line between Greenbank and Maudsland for commissioning by late 2006. This proposed augmentation has an estimated total cost of \$48.9M.

The proposed network support agreement will be valid over the summer period of 2005/06. The proposed construction timetable for the subsequent network augmentation provides for award of construction and equipment contracts in Quarter 4, 2004 and Quarter 1, 2005, commencement of on-site construction in Quarter 2, 2005 and commissioning by late 2006.

11. CONSULTATION

In accordance with Code requirements, Powerlink and ENERGEX invite submissions from Code Participants and interested parties on this Application Notice.

Submissions are due by Friday 4th June, 2004.

Please address submissions to: Manager Network Assessments

Powerlink Queensland

PO Box 1193 Virginia QLD 4014 Tel: (07) 3860 2300 Fax: (07) 3860 2388

Networkassessments@powerlink.com.au

Following consideration of submissions, Powerlink expects to publish a final recommendation in June/July 2004.

APPENDIX 1:

TECHNICAL DETAILS OF PROPOSED NEW LARGE NETWORK ASSET

Option 3A

Option 3A includes the following works:

Late 2005

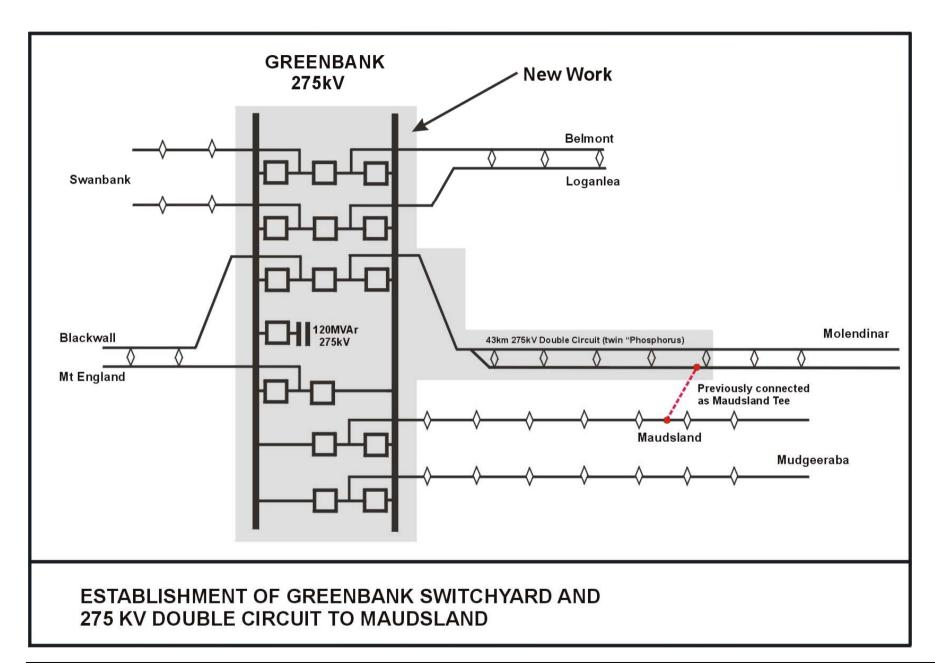

- Powerlink and the owners of DirectLink to enter into a commercial agreement for the provision of network support via import into Queensland from New South Wales over the DirectLink interconnector for the summer period of 2005/06.

Late 2006

- 43km of 275kV double circuit twin "phosphorus" conductor transmission line from Greenbank to Maudsland, including OPGW. Connection of new line to existing Maudsland Molendinar 275kV line, including disconnection of existing tee at Maudsland.
- A 275kV switchyard at Greenbank with the following:
 - o 3 x 3 circuit breaker diameters and associated equipment
 - o 3 x 2 circuit breaker diameters and associated equipment
 - o 1 x 275kV 120MVAr capacitor bank and 1 bay with associated equipment
 - protection and control systems
- connection of existing 275kV lines between Blackwall/Mt England Belmont/ Loganlea and Swanbank-Mudgeeraba into Greenbank switchyard. Necessary deviation works around Greenbank switchyard site of existing Swanbank-Mudgeeraba lines to facilitate construction of switchyard and new line
- Protection and control system modifications at 8 substation sites Molendinar, Mudgeeraba, Mt England, Blackwall, Swanbank B, Swanbank E, Belmont and Loganlea
- Establishment of dual telecommunications paths using existing and new OPGW between Greenbank switchyard and other substations connected to Greenbank.

The proposed construction timetable for these works provides for award of construction and equipment contracts in Quarter 4, 2004 and Quarter 1, 2005, commencement of on-site construction in Quarter 2, 2005 and commissioning by late 2006.

New works are highlighted in the following network configuration diagram:
